Subject: Revised ARSA Water Balance Update

Date: February 24, 2025

This Technical Memorandum (TM) provides the water balance that has been updated in response to the February 3, 2025, Central Valley Regional Water Quality Control Board (Water Board) Review of the Site-Specific Water Balance for the Amador Regional Sanitation Agency (ARSA) disposal system in joint operation with the Castle Oaks Water Reclamation Facility (COWRF) and the Castle Oaks Golf Course (COGC) which receive secondary disinfected effluent from the Sutter Creek Wastewater Treatment Plant (WWTP). This TM is organized into the following sections:

- Background Information
- WWTP Flow & Population Data
- Climatological Data
- Storage Facilities Characterization
- Disposal Facilities Characterization
- Water Balance Results

Background Information

The ARSA, City of Ione (City), and Portlock International Ltd. (Portlock) are all permittees under the State Water Resources Control Board (SWRCB) Water Reclamation Requirement Order 93-240 (WRRs). The WRRs permit the ARSA system, the COWRF, and the COGC land application areas (LAAs). ARSA operates the storage and disposal facilities downstream of the Sutter Creek WWTP, however the City operates the COWRF and Portlock operates the COGC.

ARSA's system includes conveyance infrastructure, three storage reservoirs and two LAAs. The system receives secondary disinfected effluent from the Sutter Creek WWTP and disposes of it on the Bower's Ranch and Hoskin's Ranch LAAs. Storage is provided in the ARSA system by the Henderson Reservoir, Preston Forebay and Preston Reservoir. Remaining effluent that is not disposed in the ARSA system is conveyed to the COWRF to receive tertiary treatment before it is disposed at the COGC. ARSA also owns a diversion from Sutter Creek that may divert surface water to meet irrigation demands when inadequate volume of Sutter Creek WWTP effluent is available. The Sutter Creek diversion is in need of repair and ARSA continues to seek cost effective bids for the work expected to occur in 2025 at the earliest.

Under a 2007 contractual agreement with the City, the California Department of Corrections and Rehabilitation (CDCR) Mule Creek State Prison (MCSP) has sent effluent to the COWRF either through Preston Reservoir or directly via an interconnection pipe. The discharge from MCSP to the COWRF is not described in the WRRs and is an agreement between ARSA, the City, and the CDCR. This agreement is the Parties' effort to manage the system to the maximum benefit possible. The flow diagram of the interconnected system is illustrated in Figure 1.

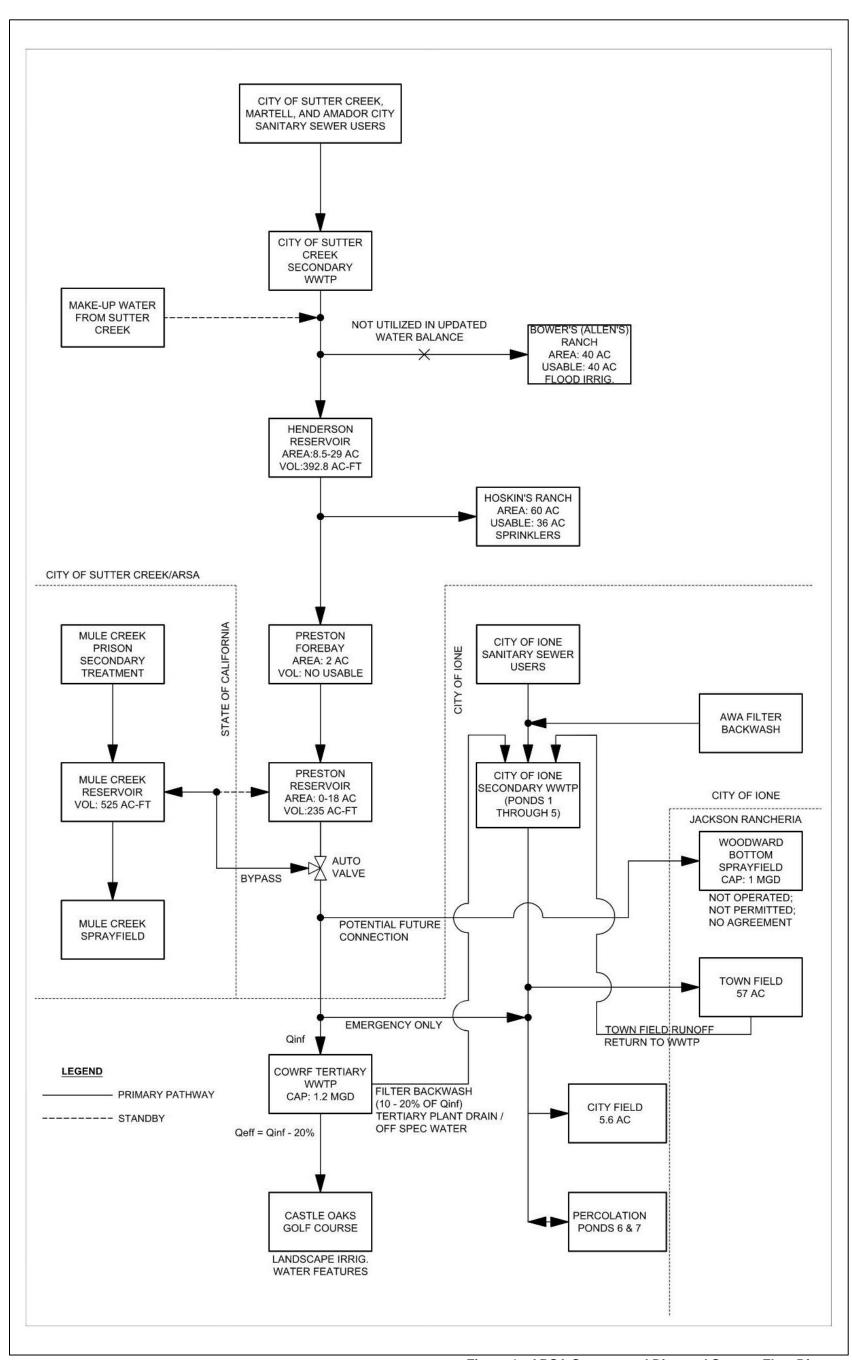

Figure 1: ARSA Storage and Disposal System Flow Diagram

On August 14, 2024, the SWRCB issued a Water Code Section 13267 Order to requiring ARSA, MCSP, and the City to verify their abilities and capacities to adequately convey, treat, and dispose of the wastewater generated by their own respective collection systems without impacting beneficial uses. ARSA, the City, and Portlock submitted the water balance by December 13, 2024, in accordance with the Water Code Section 13267 Order.

On February 3, 2025, the SWRCB issued a comment letter to ARSA, the City, and Portlock International requiring revisions to the water balance. This updated TM incorporates updates made in response to the February 3, 2025 review letter. The comments and their corresponding updated sections of this TM are summarized in Table 1 below.

WWTP Flow & Population Data

This section documents the existing wastewater flows to the Sutter Creek WWTP, and wastewater flows over the next 5 years based on population growth as required by the Water Code Section 13267 Order item 1.A. Daily flow data from January 2017 through September 2024 for the Sutter Creek WWTP and monthly status reports from January 2016 through July 2024 for ARSA facilities were provided by Sutter Creek and ARSA Staff. Population data was sourced from the California Department of Finance. Population and flow data is included as Attachment A for reference.

Current Flow Conditions

An analysis of the daily flow data indicates the Average Dry Weather Flow (ADWF) (average of flows from July through September) from 2017 through 2024 was typically 0.31 MGD.

Table 2: Sutter Creek WWTP ADWFs from 2017 Through 2024

Year	ADWF (MGD
2017	0.291
2018	0.305
2019	0.342
2020	0.269
2021	0.326
2022	0.327
2023	0.328
2024	0.318
Average	0.313

Throughout the months of December through April, Sutter Creek WWTP effluent flows can increase from infiltration and inflow (I/I) due to significant rainfall events. Precipitation data from the National Oceanic and Atmospheric Administration Sutter Hill CDF station was collected and compared to the Sutter Creek WWTP flow data. Data shown in Figure 2 indicates that once surface soils become saturated from initial rainfall, I/I increases significantly during subsequent rainfall events further into the periods of December through April.

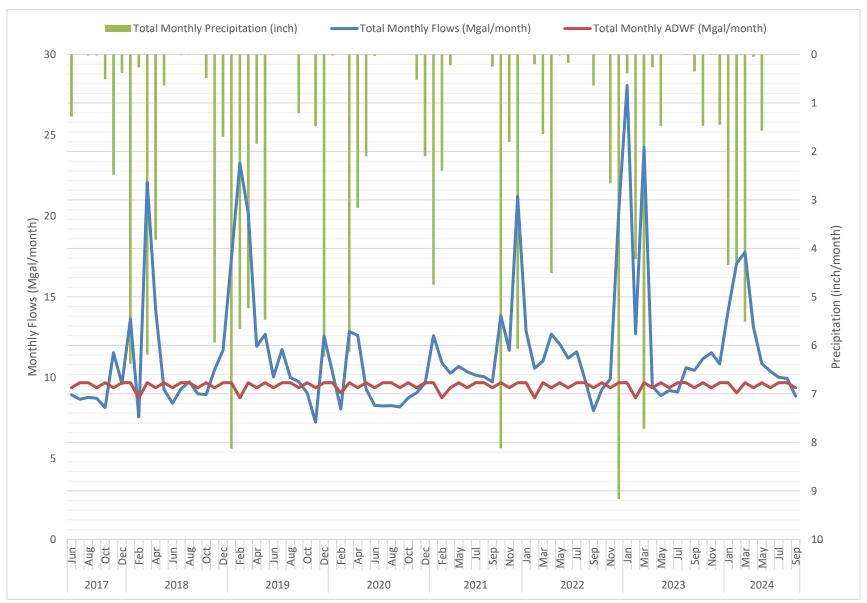

Figure 2: Sutter Creek WWTP Effluent Flows and Rainfall

To benchmark the Sutter Creek WWTP I/I, the historical wet years of 2016/17 and 2022/23 were compared to the estimated 1-in-100 Return Period (RP100) total wastewater flows. In 2016/17 water year (WY) there were 14.2 inches of precipitation from October through December before 15.1 inches of precipitation occurred in January when the peak flow of 94.8 Ac-ft also occurred. In the 2022/23 WY, there were 11.8 inches of precipitation in October through December and only 0.39" in Jan and the peak flow for the month of Jan resulted in 86.2 Ac-ft/month.

Due to the estimation of the I/I being a function of monthly precipitation, the first calibration step is adjustment of the monthly distribution of RP100 precipitation to match the 2016/17 WY rainfall patterns as described in the Climatological Data section. The climatological adjustment results in the I/I decreasing for November, March and May because the rainfall distribution for 2016/17 WY was much lower for those months. The calibrated I/I is also higher in October, December, January and April than compared to the average year because of their higher adjusted rainfall distribution.

Next, to bring the modeled RP100 flows within range of the 2016/17 and 2022/23 flows, a 25% increase in I/I from December through April was applied. This results in a January modeled peak flow of 87.4 Ac-ft which is within 8% of the 2016/17 WY peak flow. Due to the high variance and potential errors in estimating the precipitation vs I/I data, this 25% multiplier during the wet months can be considered a calibration of the modeled RP100 flows to be consistent with historical data.

As mentioned by Action Item A of the February 3, 2025, SWRCB review letter, the rainfall for January/February 2017 was much heavier than typical distribution and it may be more representative to distribute the rainfall and flow more evenly over the wet season. To evaluate the effects of rainfall distribution, RP100 rainfall and effluent flows will also be distributed based on average-year distribution and include the 25% I/I increase factor for December through April. The uncalibrated and calibrated RP100 flows and their comparative 2016/17 and 2022/23 Sutter Creek WWTP effluent flows are illustrated in Figure 3 for reference.

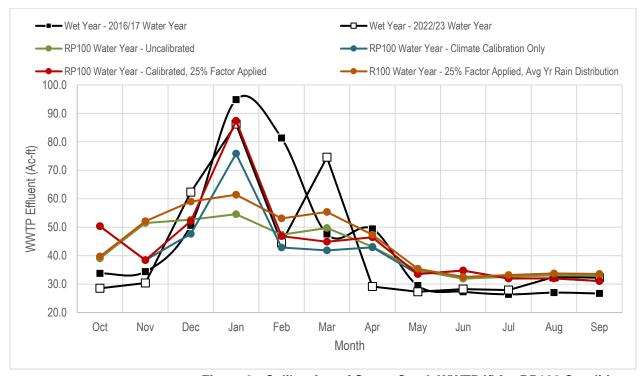

Figure 3: Calibration of Sutter Creek WWTP I/I for RP100 Conditions

Future Projected Flows & Population

In recent years the City of Sutter Creek has taken steps to reduce the I/I from the Sutter Creek WWTP collection system which included sealing of manholes within and adjacent to creek beds. Future I/I reduction efforts are expected to continue to be taken by the City of Sutter Creek, as documented in the Draft 2023 Sutter Creek WWTP I/I Analysis Update Technical Memorandum from Carollo Engineers provided as Attachment B for reference. This analysis involved flow monitoring of the collection system and modeling of the effects of I/I mitigation efforts on peak hour influent flows to the WWTP.

I/I mitigation efforts considered included manhole rehabilitation, sewer main rehabilitation or replacement and lateral rehabilitation that were recommended for sewer shed areas that have the highest I/I rates per foot of sewer pipe, which are 18% of the collection system by length. The Carollo Draft Technical Memorandum estimated the I/I reduction projects in the targeted 18% of the collection system may result in the peak hour influent flow to be reduced between 30% to 65%. However, the results of I/I reduction projects may have a more modest effect upon the peak month flows because, unlike during a peak hour event, over a peak month there may be enough time for infiltration to occur at a low rate that may still result an increased monthly influent volume.

In the prior water balance evaluation a peak month flow reduction of 5.4% was estimated for future flows, however the flow reduction has been removed due to the uncertainty of the effectiveness of the I/I reduction projects. To justify reducing the anticipated future flows (in future technical reports/analyses), the City may provide additional supporting information for the I/I reduction projects. The City may also complete additional flow monitoring after implementing the I/I reduction projects to substantiate effects on WWTP flows.

Population data provided by ARSA is sourced from the California Department of Finance population projections, which estimates in the next five years, by 2029, the population of Amador County will increase 2.17 percent.¹ The population of Sutter Creek, Martell, and Amador City are expected to increase proportionally to the projected Amador County population growth rate. The projected increases in population and flow are summarized in Table 3. ADWFs in 2029 are anticipated to reach 0.319 MGD, which is the basis of ADWF for Future Water Balance Results.

Table 3: Future Sutter Creek WWTP Flow Projections Based on Population Growth and I/I Reduction Projects

Year	ADWF (MGD)	Model Peak Month Flow (MGD)
2024	0.313	2.819
2029	0.319	2.687
Total Change	+2.17%	-4.7%

Climatological Data

This section discusses the climatological data sources and their characteristics that were used for uncalibrated and calibrated water balance calculations. Statistical depth-duration-frequency data for the RP100 frequency at 1-Year duration are referenced from the California Department of Water Resources, Ione station (station number B00 4283 00).² Precipitation for the RP100 WY totals 41.11 inches based on the Ione station. Monthly precipitation patterns and totals are based on the Western Regional Climate Center Comparative Tables for Ione.³ Average-year precipitation totals approximately 21.41 inches annually, resulting in a RP100 to average-year ratio of 1.92.

During initial water balance calculations, it became apparent that precipitation patterns during RP100 WYs did not follow the same trend as the monthly precipitation distribution during average years. The most recent historical data of a WY similar to the RP100 is the 2016/17 WY which saw 105% of the RP100 total precipitation (43.37 inches) with 15.1 inches occurring in January 2017 alone. To better fit the historically significant 2016/17 data, the RP100 precipitation pattern was adjusted to fit the monthly pattern of the 2016/17 WY, but with reduced amounts to match the statistical RP100 precipitation of 41.11 inches. The adjusted data is illustrated in Figure 4. The adjustment of the distribution of monthly precipitation for the RP100 WY is a calibration element, as mentioned in the Water Balance Results section.

A water balance using RP100 total precipitation distributed based on the average year ("Uncalibrated RP100") has also been included in the discussion of the Water Balance Results to address Required Action Item A from the SWRCB review letter.

³ Western Regional Climate Center Precipitation Comparative Tables, November 2024: <u>WRCC: Precipitation</u> Comparative Table (dri.edu)

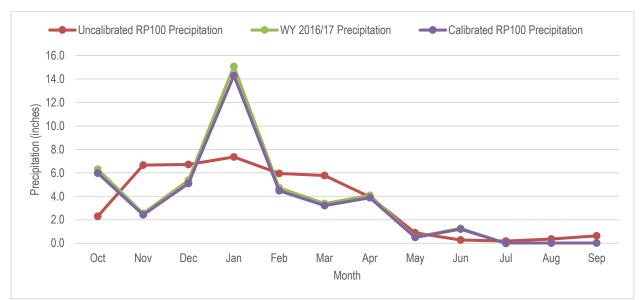

Figure 4: Calibration of RP100 Monthly Precipitation Patterns to Match 2016/17 Water Year

Pan evaporation data stations within the project vicinity are limited, therefore the Camp Pardee station was the closest selected station from the Western Regional Climate Center Pan Evaporation Comparative Tables (located within approximately 9 miles from Ione and 10 miles from Sutter Creek). Pan evaporation from the Camp Pardee station totaled 57.88 inches per year, and a typical pan coefficient of 0.75 was applied to the monthly pan evaporation data to estimate the effective lake evaporation from Henderson and Preston Reservoirs and the Preston Forebay. Additionally, a weather correction factor reduction of 25% was applied to the months of November through March during the RP100 WY to account for reduction in evaporation during a wet year wet season.

Reference evapotranspiration (Eto) data were acquired from the California Irrigation Management Information System (CIMIS) for the Shenandoah station 81, which is within 6.5 miles of Sutter Creek, and 9.5 miles of Ione and located within the Sierra Foothills, CIMIS Zone 13. The Shenandoah station reported an annual Eto total of 49.4 inches. Crop coefficients (Kc) consistent with pasture grasses for CIMIS Zone 13 were applied to the reference Eto of CIMIS station 81 to calculate crop evapotranspiration (Etc) rates at the LAAs.⁵ Wet year Kc values were used to calculate the RP100 WY Etc, and typical year Kc values were used to calculate average year Etc values. The difference between the monthly rainfall depth and the Etc resulted in the agronomic crop irrigation demand values. Rainfall efficiency is conservatively estimated at 100%, meaning all precipitation over the LAAs reaches the ground surface and is not evaporated to atmosphere. Finally, the irrigation efficiency is estimated at 85% which approximates a highly efficient irrigation system minimizing potential for overestimation of irrigation demands.

Storage Facilities Characterization

This section describes the Henderson Reservoir, Preston Forebay and the Preston Reservoir, which are the ARSA system's effluent storage facilities as illustrated in the Figure 1 flow diagram. Detailed information including topographical survey data from November 7, 2008, for Henderson Reservoir, the stage-storage curve data (for Henderson and Preston Reservoirs) and dam embankment data sheets for the reservoirs are provided in Attachment C.

Henderson Reservoir

Henderson Reservoir is reported to have a variable usable storage volume with a minimum 2 feet of freeboard from spillway ranging from 27.5 ac-ft to 392.8 ac-ft, and surface area (8.5 ac to 29 ac) based on the reservoir being at a minimum pool (approximately 5 ft stage) at the end of the dry season and at a maximum at the end of the wet season. The reservoir is described as providing seasonal storage but never to be empty. Therefore, an initial volume in any scenario was assumed to be 27.5 ac-ft and the goal of the water balance is to reach 27.5 ac-ft at the end of the dry season.

Percolation and evaporation rates are functions of the water surface area of the reservoirs; however the percolation rates are uncertain and have not been recently studied. Reservoir surface area was back-calculated from the month-to-month accumulated storage volume in the reservoir and then multiplied by the evaporation or percolation rate. The reservoir also accumulates precipitation throughout the entire acreage of 29 acres. Sutter Creek is diverted around the reservoir but a catchment area of 4.3 acres is assumed to add runoff to the reservoir with a very conservative runoff coefficient of 1.

Since Henderson Reservoir is the first reservoir in the system, the operational strategy taken in the water balance is to retain as much effluent and precipitation runoff in the reservoir throughout the wet season until full, at which point effluent would be sent from Henderson to Preston Reservoir.

Preston Forebay

The disposal capacity of the Preston Forebay is calculated as if it were only a pass-through system as the water flows through the reservoir and it maintains a constant water surface elevation and surface area. The percolation rate is reportedly zero leaving only evaporation as a means of disposal. The surface area is 2 acres with no discernible runoff catchment area.

Preston Reservoir

Preston Reservoir is reported to have a variable usable storage volume with a minimum 2 feet of freeboard from spillway ranging from 0 ac-ft to 235 ac-ft, and surface area (0 ac to 18 ac) based on the reservoir often being empty at the end of the dry season. Therefore, the initial volume in water balance scenarios was assumed to be 0 ac-ft and the goal of the water balance is to reach 0 ac-ft storage at the end of the dry season.

Amador Regional Sanitation Authority (ARSA) Revised Water Balance Update February 2025 Page 13 of 18

Similar to the Henderson Reservoir calculations, percolation and evaporation rates are a function of the water surface area of the reservoir, however the percolation rates are assumed to be negligible due to a lack of percolation studies. Reservoir surface area was back-calculated from the month-to-month accumulated storage volume in the reservoir and then multiplied by the evaporation rate. The reservoir also accumulates precipitation throughout the entire acreage of 18 acres. Preston Reservoir also has a catchment area of 14 acres that adds runoff to the reservoir with a very conservative runoff coefficient of 1.

Since Preston Reservoir is the final reservoir in the system, the operational strategy taken in the water balance is to receive any excess effluent and precipitation runoff from upstream components when Henderson Reservoir does not have available storage capacity. As a result, Preston Reservoir quickly receives large effluent volumes later in the wet season but does not reach its maximum capacity in any evaluated scenario.

Disposal Facilities Characterization

This section describes the Bower's Ranch, Hoskin's Ranch and the COGC, which are the ARSA system's effluent disposal facilities as illustrated in the Figure 1 flow diagram. Disposal capacity of each site is evaluated based on the Climatological Data section. Although Noble Ranch is described, it is not currently in use as a LAA.

Bower's Ranch

ARSA has a 40 acre land application (flood irrigation) disposal easement upon Bower's Ranch. The disposal facility was recently expanded from 60% constructed (24 acres) to fully utilizing the 40 acre site. As Bower's Ranch is the first LAA in the ARSA system, it is often fully utilized to take almost all of the Sutter Creek WWTP effluent for the months of June through October. Due to the site topography, any tailwater from the site is received by Henderson Reservoir and there is little to no risk of tailwater migrating to other properties. The site primarily consists of pasture grass that is used for cattle grazing.

As identified by Required Action Item E from the SWRCB review letter dated February 3, 2025, the water balance must include only facilities operated in compliance with WDRs and applicable regulations. Due to various compliance issues that the SWRCB asserts to exist with the current operation of Bower's Ranch, it has been removed from utilization in the water balance.

Hoskin's Ranch

ARSA has a 60 ac LAA at Hoskin's Ranch that is used for spray land application. The disposal facility was recently expanded from only 40% constructed (24 acres) to 60% constructed (36 acres). This LAA is primarily used for pasture grasses and for grazing cattle. Application rates are carefully monitored by ARSA Staff to prevent any overspray and to maintain but not exceed agronomic application rates.

Noble Ranch

Sutter Creek has an existing land application disposal easement for this site for 1,300 ac-ft/yr. This facility is not yet constructed nor is the site in use. Therefore, this site was not characterized or evaluated for water balance calculations.

Castle Oaks Golf Course

Disinfected secondary effluent from the ARSA system is exported from Preston Reservoir to the COWRF for tertiary treatment and subsequent water recycling at the COGC. The COGC includes a total irrigable acreage of 130 acres and contains nine lakes with only one lake (Lake I) totaling 3.1 acres that is typically filled with recycled water during the irrigation season. Demands to be met by ARSA's effluent include both the COGC irrigation demands and backwash flows at the COWRF which are necessary to maintain the COWRF system operation. The operation of the COWRF is detailed in Attachment D. COWRF influent flows total approximately 423.4 Ac-ft during

Amador Regional Sanitation Authority (ARSA) Revised Water Balance Update February 2025 Page 15 of 18

the RP100 WY and 481.7 Ac-ft during the average year. The capacity evaluation of the COWRF and COGC was completed by West Yost Engineers, and their 2024 COGC Recycled Water Demands Technical Memorandum is included as Attachment E for further reference. Additionally, a cover letter has been prepared by West Yost in response to the SWRCB's February 3, 2025, review letter and is included in Attachment D.

Water Balance Results

This section discusses water balance calculations that were completed for uncalibrated current flow conditions, calibrated current flow conditions, and calibrated future flow conditions. All water balance calculations consist of evaluation of system operations during a RP100 WY followed by an average year WY.

As discussed in the WWTP Flow & Population Data section, calibration of the flow data included increasing the I/I volume by 25% from December through April to be consistent with 2016/17 and 2022/23 WY flow data. Calibration of precipitation in the Climatological Data involved adjusting the monthly distribution of RP100 annual precipitation based on 2016/17 WY precipitation data. Another set of scenarios were also evaluated with RP100 annual precipitation distributed over more average-year conditions rather than the 2016/17 WY. The calibrations result in increased effluent reservoir storage volumes and increased flow I/I flow volumes. Calibrated future flow conditions account for the same I/I and climate calibrations and 2.17% population growth. As discussed in the Future Projected Flows & Population section, no I/I flow reduction has been included although the City of Sutter Creek will continue to pursue the I/I reduction projects and may provide additional information in the future to more precisely evaluate the flow effects.

The strategy of the water balance calculations incorporates the following logic:

- 1) Fully meet all irrigation demands at the LAAs (Hoskin's Ranch, and COGC) utilizing Sutter Creek WWTP effluent to the maximum agronomic rate for each given month.
- 2) Any shortfall of irrigation demands (which is also an excess of LAA disposal capacity) would be made up by water supplies other than the Sutter Creek WWTP effluent. It is assumed water supplying unmet irrigation demands are conveyed through the ARSA system, and are accounted for in monthly inflows and storage volumes. These are figurative estimates for water balance calculation purposes, and no specific water supply is identified to meet these demands.
- 3) Henderson Reservoir is assumed to maintain a minimum dead pool of 27.5 Ac-ft at 5 ft stage, whereas Preston Reservoir is allowed to reach 0 Ac-ft storage (empty).
- 4) Any excess of Sutter Creek WWTP effluent or precipitation / runoff not used to meet irrigation demands is stored in Henderson Reservoir first and then, once it reaches full capacity of 392.8 Ac-ft at 2 ft freeboard, any excess volume is sent to Preston Reservoir. Runoff and precipitation within Henderson Reservoir or its catchment area is retained in it. All other runoff and precipitation in the system in excess of monthly irrigation demand is retained in Preston Reservoir. The resulting final storage volumes for the month are then carried over as the beginning storage volume for the following month.

Amador Regional Sanitation Authority (ARSA) Revised Water Balance Update February 2025 Page 17 of 18

Water balance calculations completed for all scenarios indicate the ARSA system in combination with the COWRF and COGC can adequately contain and dispose of all Sutter Creek WWTP effluent, precipitation, and runoff for the RP100 WY without violation of storage capacity or agronomic application rates. When RP100 WY rainfall occurs on an average year distribution, the disposal capacity is decreased by approximately 0.4 Ac-ft during the irrigation season due to higher precipitation during the irrigation season which decreases the agronomic irrigation demands. However, the maximum storage required during the WY is decreased by 5.9 Ac-ft if the RP100 rainfall is distributed like an average WY.

Unlike the previous December 2024 water balance calculation, these results indicate there is only 12.5 to 13.0 Ac-ft of surplus disposal capacity (unmet irrigation demands) in the disposal system. Capacity for additional flows from other dischargers appears to be limited based on these results.

These water balance calculations do not include discharges from MCSP nor any future flows from City of Ione arising from approved housing developments exceeding existing secondary plant capacity. The remaining capacity of the COGC to accommodate flows from either of these sources is limited. The MCSP would need to utilize their sprayfields as a component of their disposal strategy, and City of Ione would need to develop additional disposal areas to address city growth. The COWRF accepting discharges from both MCSP and the City of Ione in the future is likely infeasible without large-scale expansion of the COWRF, and expansion of the COGC or development of additional LAAs.

The overall water balance results for each scenario are summarized in Table 5. Detailed water balance calculations are provided in Attachment F for further reference.

⁽¹⁾ The peak month storage volumes for Henderson and Preston Reservoirs may be in different months than the overall system's peak storage month, resulting in minor discrepancies of 2.4 to 2.9 Ac-ft between Row N values and (D+E) calculations. Where discrepancies occur, Row N displays overall peak storage month volumes from water balance calculations.

Amador Regional Sanitation Agency 2024 Individual Water Balance Update

Draft 2023 Sutter Creek WWTP I/I Analysis Update by Carollo Engineers

CITY OF SUTTER CREEK

Wastewater Treatment Plant Upgrade Project

Project No.: 12029A60

Date: October 10, 2023

Prepared By: Michael Wetterau, PE

Reviewed By: Ryan Orgill, PE; Louis Lefebvre, PE; Christina Romano, PE

Subject: Infiltration and Inflow Analysis Update

Background and Purpose

As part of the 2020 to 2021 Project Report efforts, Carollo Engineers (Carollo) developed a simple model of the collection system to estimate wet weather flow (WWF) design criteria. This information was used to conceptually size project alternative facilities evaluated in the Project Report. A typical peak wet weather flow (PWWF) factor ranges from three to six times the average daily flow (ADF). By comparison the City of Sutter Creek's (City's) PWWF is approximately 16, an order of magnitude higher than typical.

The City has been implementing infiltration and inflow (I/I) mitigation projects with the goal of reducing I/I impacts on its wastewater system. In the winter of 2023, the City performed sewer flow monitoring to help determine the areas with the highest I/I flows to further focus I/I reduction efforts. Some of the most common sources of I/I are shown on Figure 1.

Carollo was asked to review the data collected and incorporate it into the wastewater treatment plant (WWTP) project rescoping efforts. This memorandum includes the following:

- Verification of existing WWF factors.
- Identification of potential priority zones within the existing wastewater collection system for potential future I/I reduction projects.
- Development of ranges of possible WWF reduction if I/I reduction projects are implemented.

These three items are important because they could affect the size and cost of the WWTP upgrade project, as well as optimize the value of any future I/I reduction efforts. WWF factors could be used to size pumping facilities, sewage screens and grinders (i.e., headworks facilities, equalization tanks and sewer pipes). With lower WWFs, these facilities could be smaller and less costly. Understanding the areas that could be prioritized for I/I mitigation projects will increase the value of resources spent on those projects while decreasing the amount of time to observe benefits (i.e., reduced WWFs). Furthermore, I/I mitigation projects have the potential to increase the service life of existing sewers without costly replacement. Lastly, understanding the range of WWF reduction the City could see by undertaking future I/I reduction projects sets the level of expected benefit. The analysis considered historical WWTP influent flow along with temporary flow monitoring data to determine the expected WWTP influent flow during a design storm event.

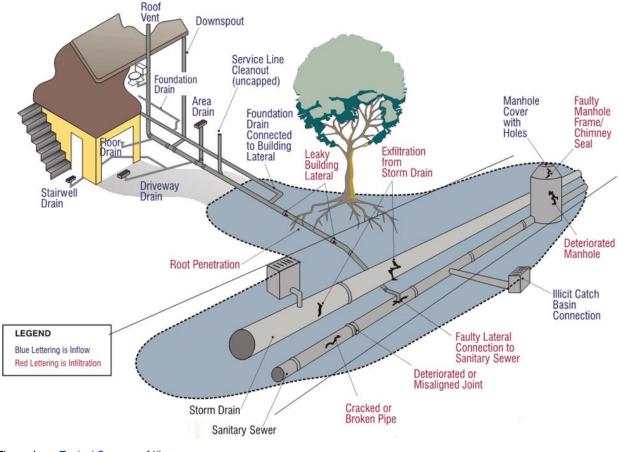

Figure 1 Typical Sources of I/I

Methods

Historical influent plant data was used to determine the dry weather flow (DWF) and WWF conditions during the monitoring period. A hydraulic model was developed using InfoSWMM¹ to model the influent flow at the WWTP for historical events. The hydraulic model's parameters were adjusted to match historical flow monitoring data.

For this project, DWF monitoring was determined based on historical plant data. Figure 2 shows the weekday and weekend hourly DWF multipliers for the entire system. A multiplier equal to 0.5 indicates at that hour of the day the flow is equal to one-half of the ADF.

¹ InfoSWMM is a fully dynamic, geospatial wastewater and stormwater modeling and management software application, which is built to run within the ESRI ArcGIS software platform. The hydraulic modeling engine for the InfoSWMM software package uses the Environmental Protection Agency's (EPA) Storm Water Management Model (SWMM), which is widely used throughout the world for planning, analysis, and design related to stormwater runoff, combined sewers, sanitary sewers, and other drainage systems. InfoSWMM routes flows through the model using the Dynamic Wave method, which solves the complete Saint Venant, one dimensional equations of fluid flow.

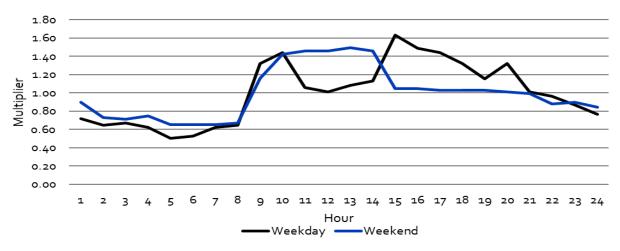

Figure 2 Weekday and Weekend DWF Hourly Multiplier

The WWF calibration consists of using actual influent WWTP flow data recorded during wet weather events, for which we have rainfall data, and adjusting model parameters so that the modeled flows match the actual flows. The model parameters are discussed later. The WWF calibration consisted of five periods with storm events. The amount of I/I is essentially the difference between the WWF and DWF components. The storm events were identified between the following dates:

- Period 1: January 2, 2017, through January 15, 2017.
- Period 2: February 5, 2017, through February 12, 2017.
- Period 3: March 12, 2018, through March 24, 2018.
- Period 4: March 1, 2019, through March 8, 2019.
- Period 5: March 9, 2023, through March 16, 2023.

The main step in the WWF calibration process includes creating a custom unit hydrograph for the City service area using the "RTK Method," which is widely used in collection system master planning. Using the RTK Method, the I/I unit hydrograph is the summation of three separate triangular hydrographs (short term, medium term, and long term), which are each defined by three parameters: R, T, and K. R represents the fraction of rainfall over the sewer basin that enters the collection system; T represents the time to peak of the hydrograph; K represents the ratio from time to peak to time of end of hydrograph. Therefore, there are a total of nine separate variables associated with a unit hydrograph. Figure 3 shows the shape of an example unit hydrograph. The WWF calibration sheets show figures comparing the measured data and model results for flow in response to rainfall. The WWF calibration sheets are included in Attachment A.

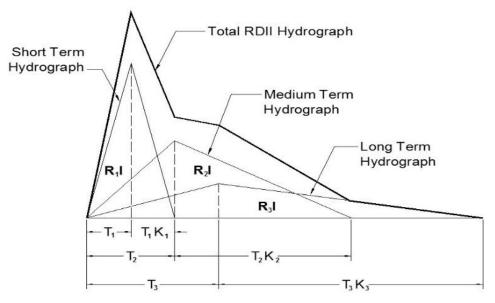

Figure 3 Example Rainfall Dependent Infiltration and Inflow (RDII) Unit Hydrograph

Design Storm

Design storms are rainfall events used to analyze the performance of a collection system under select wet weather events. The City's design storm was routed through the collection system model to determine PWWFs. The first step in the development of the design storm is to define its recurrence interval and rainfall duration. The recurrence interval is based on the probability that a given rainfall event will occur or be exceeded in any given year. For example, a "100-year storm" means there is a 1 in 100 chance that a storm as large as or larger than this event will occur at a specific location in any year.

Duration is the length of time in which the rainfall occurs. It is industry standard in California to use the 10-year, 24-hour design storm for analyzing wastewater collection system performance during PWWF conditions and for sizing some WWTP facilities (e.g., equalization tanks and pump stations). The 10-year, 24-hour design storm depth is 3.98 inches as document by National Oceanic and Atmospheric Administration (NOAA) Atlas 14.

Once the design storm recurrence interval, duration, and associated rainfall volume have been determined, the next step in defining the design storm is to distribute the total rainfall over the duration of the storm. The Natural Resources Conservation Service (NRCS) Type 1A rainfall distribution was used. Figure 4 shows the 10-year, 24-hour design storm.

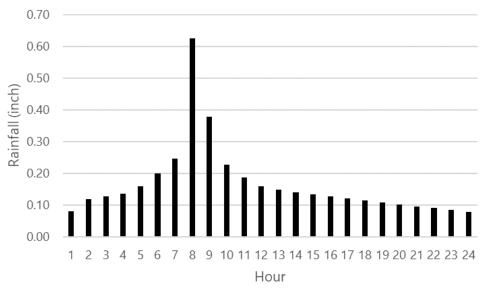

Figure 4 10-year 24-hour Design Storm Event

Hydraulic Evaluation

Following the DWF and WWF calibration of the model the design storm was applied to forecast sewer flow. The hydraulic analysis assumes all flow is conveyed to the WWTP and no flow is restricted or escapes the collection system. Figure 5 shows the peak influent flow based on the design storm at the WWTP. The model predicts that a peak hour WWF of 5.36 million gallons per day (mgd) could be observed if there were no restrictions in the collection system and if no wastewater escapes the collection system. Additionally, the model predicts that a peak day WWF of 3.16 mgd could be observed at the WWTP as a result of the 10-year, 24-hour design storm event.

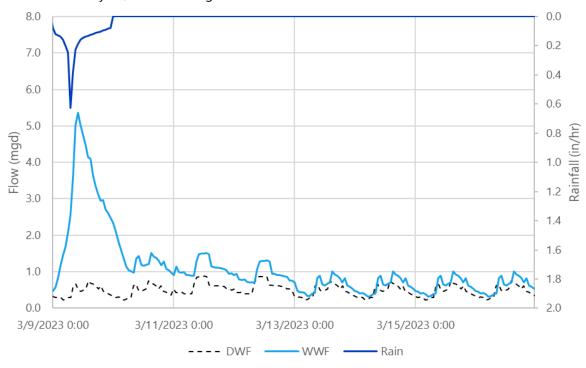

Figure 5 Modeled Influent PWWF - 10-year, 24-hour Design Storm

Temporary Flow Monitoring Program

The City completed a temporary flow monitoring program between March 8, 2023, and April 6, 2023. The flow monitoring program consisted of ten flow meters installed throughout the collection system in hopes of identifying areas in the collection system with high amounts of I/I. Table 1 summarizes the measured flow data.

Table 1 Temporary Flow Monitoring Data Summarized

Basin	Measured DWF (mgd)	Measured Peak Flow (mgd)	Peaking Factor	Pipe Length (feet)
1	0.04	0.17	4.1	0
2	0.23	1.97	8.5	18,670
3	0.07	0.16	2.3	8,010
4	0.07	0.21	3.1	7,000
5	0.01	0.13	17.9	2,960
6	0.01	0.12	9.6	3,470
7	0.18	0.76	4.1	14,480
8	0.07	0.33	5.0	4,300
9	0.08	0.46	5.5	7,020
10	0.02	0.10	5.4	10,900

Notes:

(1) Source: Flow monitoring program March 8, 2023, through April 6, 2023.

I/I Reduction

The adverse effects of I/I are that it increases both the flow volume and peak flow rate. If the City were to implement an I/I reduction program this may allow for reducing the size of some WWTP facilities (e.g., pump stations and equalization tanks). An efficient I/I reduction program will target rehabilitating the portions of the sewer collection system with the highest I/I rates. The City's sewer collection system was broken down into portions, referred to as basins (see Figure 6). I/I rates within the different basins were calculated per length of pipe in that basin. Basins 5, 6, 8, and 9 have the highest I/I rates per foot of sewer pipe and could be targeted for I/I reduction efforts. Collectively these basins account for approximately 18 percent of the total sewer collection system by length.

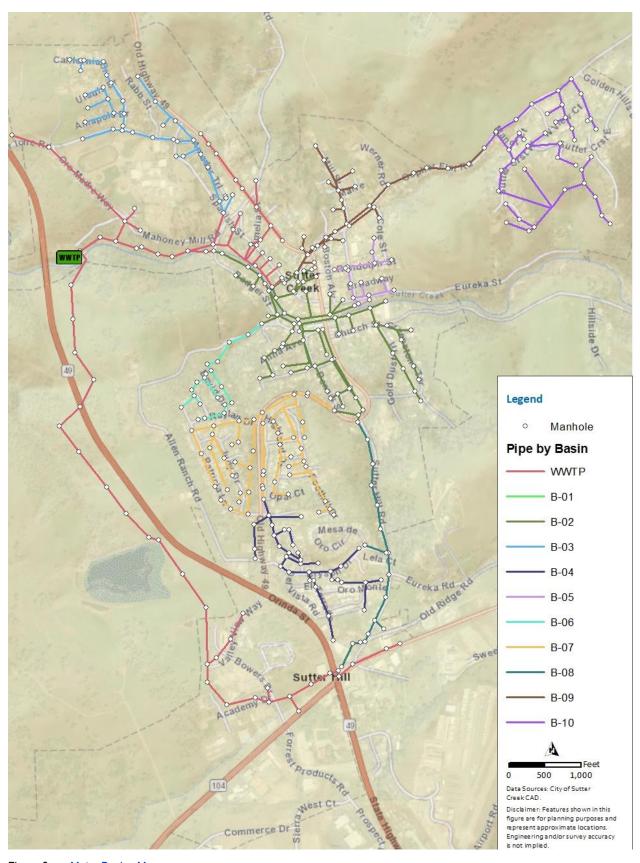

Figure 6 Meter Basins Map

There are a variety of I/I reduction techniques that can be used. I/I reduction projects can range from manhole rehabilitation to sewer main replacement/rehabilitation and lateral rehabilitation. Implementing an I/I reduction program is no guarantee that the desired I/I reduction will be achieved. However, there is a baseline benefit to rehabbing existing facilities because it would extend their life. For this analysis 30 percent and 65 percent I/I reduction in the selected basins was assumed to estimate the potential reduction in peak flows. Table 2 summarizes the potential reduction of peak influent flow at the WWTP for the range of I/I reduction assumed. Based on a review of historical literature and Carollo's experience in order to achieve an I/I reduction of 65 percent, the City may need to incorporate pipe, manhole, and service laterals rehabilitation.

Table 2 Peak Influent Flows

Scenario	Peak Influent Flow (mgd)
No Reduction	5.36
30% Reduction in Basins 5, 6, 8, and 9	4.74
65% Reduction in Basins 5, 6, 8, and 9	4.03

Conclusion

This memorandum verified existing WWFs, identified basins with highest I/I, and identified potential reductions in WWFs if I/I reduction projects are implemented in the priority basins. The planned WWTP upgrade project could expect a peak hour flow of 5.36 mgd and a peak day flow of 3.16 mgd as a result of the 10-year, 24-hour design storm.

Basins 5, 6, 8, and 9 could be prioritized for I/I reductions because I/I rates are highest in these basins. Approximately 18 percent of the total sewer collection system length is in these basins. If I/I is reduced in these basins between 30 percent and 65 percent a reduction in peak hour flow between 0.62 mgd and 1.33 mgd could be realized.

Kari.Holmes@waterboards.ca.gov

Subject: Certification Letter for Castle Oaks Golf Course Recycled Water Demands

Dear Ms. Holmes,

On August 14, 2024, the Central Valley Water Quality Control Board (Regional Board) issued a 13267 Order letter to the City of Ione (City), Amador Regional Sanitation Agency (ARSA) and Portlock International Ltd. (Portlock), the three entities permitted the Regional Board under Water Reclamation Requirement Order 93-240 (WRRs) to land apply recycled water from the Castle Oaks Water Reclamation Facility (COWRF) to the Castle Oaks Golf Course (golf course). The City owns and operates the COWRF, which provides the recycled water to the golf course. The City also owns the golf course, which is leased and operated by Portlock. ARSA is permitted to supply water to the COWRF to meet the irrigation needs of the golf course.

The 13267 Order requires that the three WRRs permittees submit an updated water balance for the ARSA system to the Regional Board by December 13, 2024. Most of the required information under the 13267 Order does not pertain to the COWRF or golf course operations. Consequently, ARSA lead the development of the response required under the 13267 Order.

To address requirements specific to the City-led operations, the City previously submitted the *Castle Oaks Golf Course Recycled Water Demands Technical Memorandum* (Water Demands TM) that provided information and supporting documentation for the following topics:

- Historical and theoretical influent flows to the COWRF,
- Historical and theoretical recycled water use at the Golf Course,
- Agronomic water demands of the Golf Course,
- Storage capacity and operation of the Golf Course recycled water storage ponds, and

• Golf Course tailwater and overspray control and monitoring – including BMPs to minimize runoff or overspray and practices to improve the application of recycled water to the use area.

On February 3, 2025, the Regional Board issued a letter titled *Review of Site-Specific Water Balance, Amador County Regional Outfall And Castle Oaks Golf Course And Development, City Of Ione/Amador Regional Sanitation Authority/Portlock Int. LLC., WDR 93-240, Amador County.* This letter documented additional information that must be addressed in the site-specific water balance. The specific items identified that apply to the City's operation and the City's response to these items are summarized in the table below.

Summary of Responses to Regional Board Comments Regional Board Comment City Response The City of Ione is currently Title 22 includes the following setback distance developing a Title 22 Engineering requirements applicable to disinfected tertiary recycled Report for the use of recycled water: water produced at the COWRF on No irrigation with disinfected tertiary recycled the COGC. Title 22 requires water shall take place within 50 feet of any setbacks for the irrigation of domestic water supply well. recycled water near water No impoundment of disinfected tertiary recycled courses, residential areas, and water shall occur within 100 feet of any domestic public spaces. It is unclear if the water supply well. acreage used to calculate the Any use of recycled water shall comply with the COGC disposal capacity following: considers these setbacks. More Any irrigation runoff shall be confined to the information shall be submitted, recycled water use area, unless the runoff does and the water balance shall be not pose a public health threat and is authorized updated accordingly as needed. by the regulatory agency. Spray, mist, or runoff shall not enter dwellings, designated outdoor eating areas, or food handling facilities. Drinking water fountains shall be protected against contact with recycled water spray, mist, or runoff. As part of development of the Title 22 Report, the City's consultant team West Yost Associates comprised of crossconnection control specialists conducted surveys of the golf course to confirm setback distance requirements were being satisfied. The irrigated acreages used in the water balances were developed from the information obtained during this survey. There are no known domestic water supply wells within 50-feet of the use area (or within 100 feet of the irrigation impoundments). The team also observed spray irrigation

practices and confirmed there was no evidence of spray mist or runoff entering enter dwellings, designated

Summary of Responses to Regional Board Comments	
Regional Board Comment	City Response
	outdoor eating areas, or food handling facilities or drinking fountains.
	Based on this information, the setback distances do not need to be modified to meet the requirements of Title 22. The existing irrigated acreages used in the water balances were developed from the information obtained during this survey. These acreages do not need to be modified to conform to Title 22.
	Additional details will be included in the Title 22 Report.
	No change is required to address this statement.
The submittal indicates that COGC has an "overflow" from one of the recycled water holding ponds into Mule Creek. This is an unpermitted discharge and cannot be used as part of the water balance. The submittal also states "In addition, the recycled water remaining in Lake I at the end of the irrigation season is diluted with 1.2 million gallons of potable water. Golf course staff reported that this practice was developed in partnership with the California Department of Health Services to minimize the potential for discharge of recycled water to surface waters." No such practice has been permitted by the Department of Health Services (now the Division of Drinking Water, or DDW) nor the Central Valley Water Board. It is inaccurate to state that the Discharger believed this to be an approved discharge, as an NOV was issued for the same discharge on 28 January 2020. This discharge must cease immediately, the water balance shall be updated appropriately.	The City understands the Board's direction that the "dual use" of the ponds on the golf course is not an approved discharge and must cease. Importantly, for purposes of addressing comments on the updated water balance for the ARSA system, discharge from these ponds was not accounted for in the City's water balance. Accordingly, no revision is required to the water balance to address the Regional Board's comment. Moving forward, the City will reach out to and coordinate with the Regional Board, DDW, and the golf course to take action to address the prohibited discharge. Development of such action(s) may be appropriate as part of the preparation and finalization of the City's Title 22 Report.

"I certify under penalty of law that I have personally examined and am familiar with the information submitted in this letter and that, based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment."

Sincerely,

George Lee, City Manager

Subject: Certification Letter for Castle Oaks Water Reclamation Facility Capacity and Operations TM, Water Reclamation Requirement Order 93-240

Dear Mr. John Baum,

On August 14, 2024, the Central Valley Water Quality Control Board (Regional Board) issued a 13267 Order letter to the City of Ione (City), Amador Regional Sanitation Agency (ARSA) and Portlock International Ltd. (Portlock), the three entities permitted the Regional Board under Water Reclamation Requirement Order 93-240 (WRRs) to land apply recycled water from the Castle Oaks Water Reclamation Facility (COWRF) to the Castle Oaks Golf Course (golf course). The City owns and operates the COWRF, which provides recycled water to the golf course. The City also owns the golf course, which is leased and operated by Portlock. ARSA is permitted to supply water to the COWRF to meet the irrigation needs of the golf course.

The 13267 Order requires that the three WRRs permittees submit an updated water balance for the ARSA system to the Regional Board by December 13, 2024. The letter specifies six items (A through F) that must be provided. The attached *Castle Oaks Water Reclamation Facility Capacity and Operations Technical Memorandum* (Capacity Operations TM) addresses the requirements under Item D of this letter, which states the following information must be provided:

The current and expected treatment capacity and operation schedule of the tertiary treatment plant. These numbers should be provided and certified by Ione. Supporting documentation must be included.

The City of Ione, City Manager has reviewed the contents of the Capacity Operations TM and provides the following certification statement:

I certify under penalty of law that I have personally examined and am familiar with the information submitted in this document and all attachments and that, based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment.

Sincerely,

George Lee

TECHNICAL MEMORANDUM

DATE: December 9, 2024 Project No.: 988-50-24-10

SENT VIA: EMAIL

TO: George Lee, City of Ione

FROM: Ileana Wald, PE, RCE #97046

REVIEWED BY: Kathryn Gies, PE, RCE #65022

SUBJECT: Castle Oaks Water Reclamation Facility Capacity and Operations Summary

This technical memorandum (TM) provides information and supporting documentation related to the capacity and operations of the Castle Oaks Water Reclamation Facility (COWRF), which is owned and operated by the City of Ione (City). The purpose of this TM is to inform development of a water balance for the Amador Regional Sanitation Authority (ARSA) wastewater disposal system. The following topics are addressed:

- Background Information
- Treatment Facilities Description
- Recycled Water Treatment Operations
- Treatment Capacity Summary

BACKGROUND INFORMATION

Facility Overview

The COWRF is a tertiary-only recycled water treatment plant located at 10100 Five Mile Drive in Ione, Amador County, California (see Figure 1, Vicinity Map). The facility receives disinfected secondary treated wastewater that is further treated through coagulation, filtration, and chlorine disinfection processes. A schematic diagram, hydraulic profile and design criteria for the COWRF that were included in the As-Built drawing set are included as Attachment A.

The COWRF produces "Disinfected Tertiary Recycled Water" as defined under the California Code of Regulations (CCR), Title 22 for irrigation use at the Castle Oaks Golf Course (golf course), which is leased and operated by Portlock International Ltd. (Portlock). There are no other uses or use areas. The City's Wastewater Treatment Facility (WWTF) is located adjacent to the COWRF but does not presently send treated effluent to the COWRF for treatment.

Prepared for:

Regulatory History

The City, ARSA and Portlock are the three entities permitted the Central Valley Water Quality Control Board (Regional Board) under Water Reclamation Requirement Order 93-240 (WRRs) to discharge recycled water from the COWRF to the golf course. ARSA is specifically permitted to supply secondary treated wastewater to the COWRF to meet the irrigation needs of the golf course.

On August 14, 2024, the Regional Board issued a 13267 Order letter to the three WRRs permittees that requires the submission of an updated water balance for the ARSA system to the Regional Board by December 13, 2024. The letter specifies six items (A through F) that must be provided. This TM addresses the requirements under Item D of this letter, which states the following information must be provided:

The current and expected treatment capacity and operation schedule of the tertiary treatment plant. These numbers should be provided and certified by Ione. Supporting documentation must be included.

TREATMENT FACILITIES DESCRIPTION

The treatment process train consists of preliminary screening, chemical coagulation, direct sand filtration, and chlorine disinfection. The layout of COWRF's treatment facilities are shown on Figure 2. The major treatment components of the COWRF include:

- Influent flow control and screening,
- Coagulation/flocculation,
- Filtration,
- Chlorine disinfection,
- Effluent pumping, and
- Solids treatment and handling.

Influent Flow Control and Screening

The COWRF headworks structure includes a magnetic flow meter, a pneumatically operated butterfly valve for flow control, screens, and an influent sample tap. The flow through the COWRF is controlled by the butterfly control valve and is based on an operator-set target flow rate. The flow rate is set to match the demand from the golf course. The valve will shut automatically in the event of a critical process failure (high liquid levels, high turbidity, or low chlorine residual) or power outage.

One static parabolic screen is provided to remove large solids prior to filtration. The screen opening size is 0.10 inch and the stated capacity of the screen is 1,350 gallons per minute (gpm).

Coagulation/Flocculation

Screened recycled water flows by gravity to the rapid mix chamber. Alum and/or polymer are added downstream of the static screen and prior to rapid mixer that promotes coagulation of the solids. Additional polymer can also be added before recycled water flows through two mechanical flocculation chambers. The signal from the influent flow meter is used to automatically flow pace the alum and polymer metering pumps to achieve a desired dosing rate. Adjustments to the dosing rate can be made by the operators based on measured filter effluent turbidity.

0 100 200 N Feet

TM – City of Ione December 9, 2024 Page 5

Filtration

After flocculation, recycled water flows from the flocculation chambers by gravity through the tertiary filters. The tertiary filtration system consists of continuous backwash, upflow, deep bed, and granular media DynaSand filters manufactured by Parkson Corporation. There are four filter cells, each containing two 50 square feet (ft²) filter modules. The filter cells are operated in parallel with three duty and one standby unit. The design filtration rate for each filter cell is 2.8 gallons per minute per square foot (gpm/ft²); however, each filter unit should be able to process up to 5 gpm/ ft².

The Parkson Dyansand filter is approved for the production of disinfected tertiary recycled water, as documented in a letter dated December 1, 1986, from the CDPH Drinking Water Program (now known as DDW)¹. Additional design criteria for the tertiary filtration system is summarized in Attachment A.

Compressed air is used for continuous backwashing of a portion of the sand medium. Backwash (filter reject) from the filters is collected in a common trough and flows by gravity to the filter backwash clarifier. The filter reject stream is expected to be 5 to 10 percent of the total plant flow². However, the filter reject flows are measured, and this data indicates that backwash flows are 10 to 20 percent of the total plant flow.

Chlorine Disinfection

After filtration, recycled water flows to the chlorine mixing chamber where the sodium hypochlorite solution is added. The sodium hypochlorite solution dosing pumps are flow paced to the plant influent flow meter to achieve a desired dosing rate. Adjustments to the dosing rate can be made by the operators based on measured final effluent chlorine residual. A high-speed mechanical mixer in the chlorine mixing chamber ensures that the chlorine solution is well mixed with the recycled water flow.

After mixing, recycled water enters the Chlorine Contact Basin (CCB), which is a concrete basin with a serpentine, rectangular shape (Figure 3). The CCB is divided into two halves (CCB-1 and CCB-2) which could be operated individually in parallel or together in series. However, the two basins are exclusively operated in series. Each half can also be isolated and operated independently when the other needs to be drained for maintenance. However, CCB maintenance is typically done when the COWRF is offline.

The total volume of the CCB is reported as a nominal 100,000 gallons³. The channels are 6 feet wide and 6 feet deep and are separated by 8-foot-high concrete baffle walls. However, the detailed record drawings for the COWRF⁴ show that the CCB operating volume is approximately 112,000 gallons, with a length-to-width ratio of 66 to 1. At the COWRF's design flow of 1.2 million gallons per day (MGD), the CCB's hydraulic retention (HRT) time is 134 minutes. The HRT in the CCB is controlled solely by the influent flow rate. The fixed volume of water in the CCB is controlled by a slide gate in each CCB half that allows water to overflow into the effluent clear well. If only one half of the CCB is operated (CCB-1 or CCB-2), the maximum flow that can be treated is 0.6 MGD.

A tracer study will be conducted to demonstrate modal contact time for flow through CCB for compliance with CCR, Title 22, Section 60301.230.a.1. The tracer study protocol was submitted to the State Water Resources Control Board (SWRCB), Division of Drinking Water (DDW) for review on October 1, 2024. The tracer study will be conducted in winter 2024/2025, the results of which will be incorporated into an updated Title 22 Engineering Report.

Chlorine Contact Basin Flow Schematic

City of Ione COWRF Capacity and Operations TM TM – City of Ione December 9, 2024 Page 7

Effluent Pumping

Downstream of the CCB effluent weir, the disinfected recycled water enters the effluent pump station wet well. There are two effluent pumps, each rated at 850 gpm. Therefore, each pump can convey the entire treatment flow of 1.2 mgd to the golf course.

The effluent flow meter that was originally installed at the COWRF was not capable of providing an accurate flow measurement in its configuration. Therefore, the City historically reported effluent flow as influent flow. With the adoption of the current Monitoring and Reporting Program in October 2021, the City began reporting the effluent flow as the difference between the influent flow and the measured filter backwash flow at the start of the 2022 irrigation season. The City recently replaced the effluent flow meter and will initiate using this flow meter to report effluent flow in the 2025 irrigation season.

Solids Treatment and Handling

The filter backwash stream is routed to the Filter Backwash Clarifier, where suspended solids are removed in the through settling. The solids concentration of the filter reject stream is estimated to be 400 to 600 mg/L and the maximum alum sludge loading from the filter is projected at 300 to 1,000 lb/day.

Overflow from the Filter Backwash Clarifier is discharged to the plant drain system that leads to the Decant Pump Station. The pump station discharges the backwash flow to the City of Ione WWTF collections system, where it is combined with raw wastewater and directed to the WWTF for treatment.

Sludge from the Filter Backwash Clarifier is pumped to one of the three sludge drying beds. After drying, the sludge is stored and eventually disposed of in a landfill. An under-drain on Sludge Drying Beds 1 and 2 returns decanted water by gravity to the Decant Pump Station. Sludge Drying Bed 3, constructed in 2002, is provided with an integral sump to return decant water to the Filter Backwash Clarifier.

RECYCLED WATER TREATMENT OPERATIONS

Secondary effluent is stored prior to discharge to the COWRF. As such, the influent flow does not follow a diurnal pattern. Instead, flow through the plant is steady throughout the day. As previously noted, the influent control valve is used to set the desired influent flow rate to the COWRF based on the demands of the golf course.

The COWRF is in operation when there is irrigation demand at the golf course, typically April through November. Recent flow rates at the COWRF from available Daily Monitoring Report (DMR) data from January 2018 through October 2023⁵ are summarized on Figure 4. As previously noted, influent flow was reported as effluent flow prior to April 2022 and starting in 2022 effluent flows have been calculated. The maximum daily influent flow to the COWRF was approximately 1.25 MGD in January 2018. For months where no influent or effluent flows are shown, the COWRF was offline.

⁵ DMR data for May 2023 at COWRF was not available.

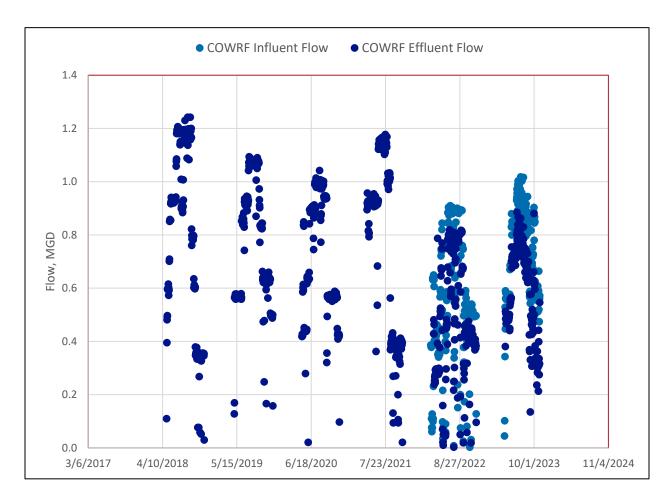

Figure 4. Recent COWRF Flows

WEST YOST N-C-988-50-24-10-WP-CAPACITY AND OPERATIONS TM

Monthly average effluent flows from COWRF are summarized in Table 2. In recent years the average monthly flow through the COWRF ranged from 0.43 MGD to 0.95 MGD.

Table 2. Monthly Average Effluent Flows from COWRF							
Month	Effluent Flow ^(a,b) , MGD						
January	-						
February	-						
March	-						
April	0.53						
May	0.63						
June	0.82						
July	0.95						
August	0.92						
September	0.68						
October	0.48						
November	0.43						
December	-						

a) Data from available DMR data averaged over period between January 2018 and October 2023. The sole flow meter is located at the influent pump station. Prior to April 2022, influent flow was reported as effluent flow. Starting in 2022, effluent flows have been estimated.

TREATMENT CAPACITY

The COWRF is designed to treat an average peak flow of 1.2 MGD. The facility's treatment capacity is primarily limited by the CCB capacity.

Rancho Cordova, CA

Subject: Certification Letter for Castle Oaks Golf Course Recycled Water Demands

Dear Mr. John Baum,

On August 14, 2024, the Central Valley Water Quality Control Board (Regional Board) issued a 13267 Order letter to the City of Ione (City), Amador Regional Sanitation Agency (ARSA) and Portlock International Ltd. (Portlock), the three entities permitted the Regional Board under Water Reclamation Requirement Order 93-240 (WRRs) to land apply recycled water from the Castle Oaks Water Reclamation Facility (COWRF) to the Castle Oaks Golf Course (golf course). The City owns and operates the COWRF, which provides the recycled water to the golf course. The City also owns the golf course, which is leased and operated by Portlock. ARSA is permitted to supply water to the COWRF to meet the irrigation needs of the golf course.

The 13267 Order requires that the three WRRs permittees submit an updated water balance for the ARSA system to the Regional Board by December 13, 2024. The letter specifies six items (A through F) that must be provided. Most of the required information under the 13267 Order does not pertain to the COWRF or golf course operations. Consequently, ARSA is leading the development of the response required under the 13267 Order, which will be presented separately. The attached *Castle Oaks Golf Course Recycled Water Demands Technical Memorandum* (Water Demands TM) only addresses the requirements under Item B of the 13267 Order, which states:

The acreage and agronomic rate at which recycled water can be applied to the Castle Oaks Golf Course without violating setback requirements, Title 22 requirements, impacting groundwater, or causing runoff to surface water. These numbers and calculations should be provided and certified by Ione and Portlock

International LTD. Supporting documentation and references must be included in the submittal. Information regarding tailwater control/return and monitoring plans for compliance with applicable land application area requirements must also be included.

The Water Demands TM provides information and supporting documentation for the following topics:

- Historical and theoretical influent flows to the COWRF,
- Historical and theoretical recycled water use at the Golf Course,
- Agronomic water demands of the Golf Course,
- Storage capacity and operation of the Golf Course recycled water storage ponds, and
- Golf Course tailwater and overspray control and monitoring including BMPs to minimize runoff or overspray and practices to improve the application of recycled water to the use area.

The City of Ione has reviewed the contents of the attached Water Demands TM and provide the following certification statement:

"I certify under penalty of law that I have personally examined and am familiar with the information submitted in this document and all attachments and that, based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment."

Sincerely,

George Lee

City Manager

TECHNICAL MEMORANDUM

DATE: December 10, 2024 Project No.: 988-50-24-10

SENT VIA: EMAIL

TO: George Lee, City of Ione

CC: Daniel Griffin, Castle Oaks Golf Course

Justin Granados, WaterStone Service

FROM: Allie Ahern, EIT

REVIEWED BY: Kathryn Gies, PE, RCE #65022

SUBJECT: Castle Oaks Golf Course Recycled Water Demands

This technical memorandum (TM) provides information and supporting documentation related to water needs of the Castle Oaks Golf Course (golf course), which receives recycled water from the Castle Oaks Water Reclamation Facility (COWRF). The purpose of this TM is to inform development of a water balance for the Amador Regional Sanitation Authority (ARSA) wastewater disposal system. The following topics are addressed:

- Background Information
- Golf Course Irrigable Acreage
- Golf Course Storage Ponds
- Golf Course Agronomic Water Demands
- COWRF Influent Flows
- Golf Course Tailwater and Overspray Control and Monitoring

BACKGROUND INFORMATION

This section provides background information relevant to this TM. The following topics are addressed:

- Regulatory History
- Applicable Regulatory Standards for Water Balances
- Golf Course Demands vs. COWRF Influent Flows

Regulatory History

The City of Ione (City), ARSA and Portlock International Ltd. (Portlock) are the three entities permitted the Central Valley Water Quality Control Board (Regional Board) under Water Reclamation Requirement Order 93-240 (WRRs) to land apply recycled water from the COWRF to the golf course. The City owns and operates the COWRF, which provides the recycled water to the golf course. The City also owns the golf course, which is leased and operated by Portlock. ARSA is permitted to supply water to the COWRF to meet the irrigation needs of the golf course.

On August 14, 2024, the Regional Board issued a 13267 Order letter to the three WRRs permittees that requires the submission of an updated water balance for the ARSA system to the Regional Board by December 13, 2024. The letter specifies six items (A through F) that must be provided. This TM addresses the requirements under Item B of this letter, which states:

The acreage and agronomic rate at which recycled water can be applied to the Castle Oaks Golf Course without violating setback requirements, Title 22 requirements, impacting groundwater, or causing runoff to surface water. These numbers and calculations should be provided and certified by Ione and Portlock International LTD. Supporting documentation and references must be included in the submittal. Information regarding tailwater control/return and monitoring plans for compliance with applicable land application area requirements must also be included.

Applicable Regulatory Standards for Water Balances

The 13267 Order states that the water balance must be in compliance with the requirements and guidance of the Regional Board's guidance document *Requirements for Water Balance Update and Calibration*, which is provided as Attachment A to the 13267 Order. Several of the procedures defined in this guidance document are applicable to the development of this TM, as follows:

Requirements for Water Balance Update and Calibration, Section 4:

The normal operations and maintenance of land application areas should be considered. [Operations and Maintenance] O&M Manuals should be referenced as well as historical monitoring data (i.e. percolation rates, observed standing water). Specific conditions of the [WRRs] should also be taken into account. The following should be taken into consideration:

- A. Recycling area/land application area/disposal system hydraulic loading rates should be distributed monthly in accordance with expected seasonal variations based on crop evapotranspiration rates.
- B. The distribution of precipitation (i.e. storm intensity, light rain over a lot of days or heavy rain over a few days), as well as other factors such as wind and saturated conditions must be taken into account when determining the number of days a disposal system can be operated each month. The most reliable way to estimate this is based off of historical records from a water year of intensity similar to that which is being modeled.
- C. It should be specified whether the tailwater is collected, and if so if it is returned to the sprayfields directly or to one of the ponds.
- D. If applicable, storm water runoff shall be accounted for in the tailwater return calculations.
- E. Maximum disposal capacity of land application areas should be based on soil studies, cropping plans, percolation studies, and/or operator notes.

TM – City of Ione December 10, 2024 Page 3

Requirements for Water Balance Update and Calibration, Section 5:

A. All water balances shall start on 1 October and end on 30 September.

..

- C. The water balance should include an assessment of the facility's capacity and performance during a normal water year and during a year with a total annual precipitation for a return period of 100 years.
- D. Local precipitation data for the 100-year annual return period, distributed monthly in accordance with mean monthly precipitation patterns shall be used. However, periods of high intensity storms should also be considered in the calculations.
- E. All water balances should be based on all available data. All data should also be quality controlled and used with discretion.

...

- G. For each wastewater treatment, storage, or disposal pond and containment structure, provide the following information:
 - a. Identification (name) and function of the pond.
 - b. Surface area, depth, and volumetric capacity at two feet of freeboard.
 - c. Height (relative to surrounding grade), crest width, interior slope, and exterior slope of each berm or levee.
 - d. Materials used to construct each berm or levee.
 - e. Description of engineered liner, if any. Include a copy of the Construction Quality
 - f. Estimated steady state percolation rate for each unlined pond.
 - g. Depth to shallow groundwater below the base and pond inverts.
 - h. Precipitation and evapotranspiration data shall be from recognized stations. The source of this information shall be provided, including a link to the data.
 - i. Overfilling/overflow prevention features.
 - j. Operation and maintenance procedures.

Golf Course Demands vs. COWRF Influent Flows

During the COWRF tertiary treatment process, a fraction of the influent to the COWRF is discarded as filter backwash and sent to the City of Ione's Wastewater Treatment Facility (WWTF). The remaining influent to the COWRF is treated to tertiary standards and recycled at the golf course. Therefore, the influent flow to the COWRF needs to be greater than the agronomic water demand of the golf course to accommodate the losses due to filter backwash, and the ARSA water balances need to include the portion of influent sent as filter backwash to the WWTF.

The City is concurrently in the process of preparing a water balance for its WWTF in accordance with a separate 13267 Order. The WWTF water balance will also need to account for the COWRF backwash flows. Accordingly, this TM presents calculations that define both the COWRF influent flows needed to meet the golf course agronomic demands for use in the ARSA water balance and the backwash flow from the COWRF to the WWTF for use in the WWTF water balance.

TM – City of Ione December 10, 2024 Page 4

GOLF COURSE IRRIGABLE ACREAGE

The irrigable acreage of the golf course was determined based on inspection of the golf course irrigation system and discussions with staff. This area was mapped and quantified using GIS mapping and data processing tools. Figure 1 presents the map created. The following areas of the golf course were not included in the calculated irrigable acreage:

- natural, undeveloped areas surrounding Mule Creek and Sutter Creek
- areas abutting residences surrounding the golf course; some of these areas are irrigated by residents while others remain unirrigated
- hardscape and permanent water features

The total irrigable area of the golf course was determined to be 130 acres.

WEST YOST

City of lone Castle Oaks Golf Course Recycled Water Demands

Castle Oaks Golf Course Irrigable Area Figure 1

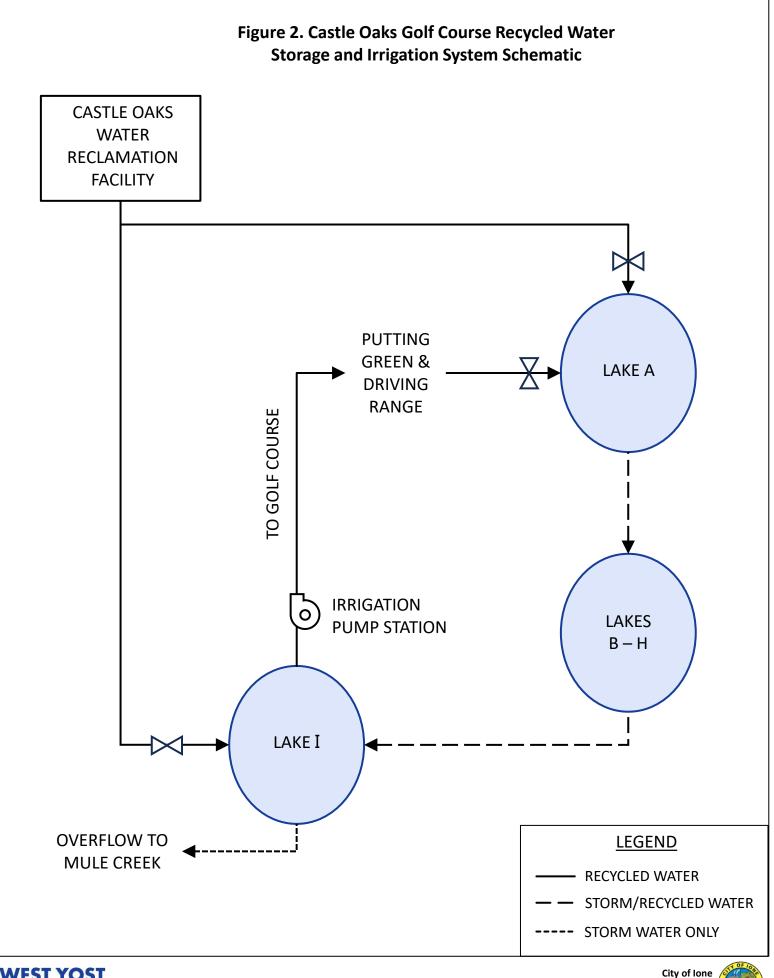

GOLF COURSE STORAGE PONDS

The golf course has nine ponds that can be filled with recycled water during the irrigation season. The ponds serve as aesthetic features and water hazard obstacles for the golf course and are used to hold recycled water before it is pumped to the golf course. Limited construction information is available for the ponds, but the ponds are understood to be unlined and constructed of native soil material. Estimates of the depth, volume and percolation rates of the ponds are not available. However, it is estimated that on average, the depth of groundwater below the golf course ranges from 8 to 13 feet. The surface area of each pond has been estimated using GIS mapping and data processing tools and is presented in Table 1.

Table 1. Golf Course Storage Pond Surface Area							
Pond Name	Surface Area, acres						
Lake A	0.8						
Lake B	1.2						
Lake C	0.4						
Lake D	1.1						
Lake E	2.2						
Lake F	1.1						
Lake G	1.6						
Lake H	1.4						
Lake I	3.1						

The ponds are hydraulically connected to each other. The maximum water level of each pond is controlled by a fixed standpipe located in an access port approximately 20 to 100 feet from the lake's edge. Water overflowing the standpipe of the upstream lake is conveyed by to the following lake downstream, with Lake A being the furthest upstream lake, and Lake I being the furthest downstream lake. The Lake I overflow standpipe connects to a wetlands area that is tributary to the nearby surface water body Mule Creek. Figure 2 presents a schematic of the recycled water irrigation system.

Recycled water from the COWRF can be pumped directly to either Lake I or Lake A. Recycled water is then pumped from Lake I to the golf course irrigation system. Under current operations, recycled water is sent by default to Lake I. Golf course staff relate that recycled water is only pumped to Lake A for short periods during the irrigation season, when golf course demands are not keeping up with flows from the COWRF and Lake I is at risk of overflowing. Typically, recycled water that is directed to Lake A will remain in the Lake until it has percolated or evaporated. However, recycled water can discharge from Lake A to the downstream lakes if Lake A overflows. However, golf course staff indicate that the amount of recycled water flow sent to Lake A is not enough to result in overflows.

TM – City of Ione December 10, 2024 Page 8

The ponds also serve as catchment for stormwater runoff the golf course. During the winter rainfall season, stormwater runoff will fill the nine ponds, and they will eventually overflow to Mule Creek. To prevent the discharge of recycled water to Mule Creek, recycled water is only delivered to the golf course during the irrigation season (typically between April and October). This allows for water in Lake I to percolate and evaporate before the rainy season begins. In addition, the recycled water remaining in Lake I at the end of the irrigation season is diluted with 1.2 million gallons of potable water. Golf course staff reported that this practice was developed in partnership with the California Department of Health Services1 to minimize the potential for discharge of recycled water to surface waters.

GOLF COURSE AGRONOMIC WATER DEMANDS

Calculation Procedures

The steps and major assumptions used to determine the rate at which recycled water can be supplied to the golf course are described below.

Climate Data

Rainfall data reported by the Ione National Climate Data Center (NCDC) weather station #0442832 was used to define the average annual rainfall, 1-in-100-year annual rainfall, and the monthly distributions of rainfall, as follows:

- The average rainfall year was defined as having a total rainfall of 22.0 inches.
- The 1-in-100 rainfall year was defined as having a total rainfall of 41.1 inches.
- The monthly distributions were defined based on the 1906 to 1977 monthly Normal rainfall distribution values, with the Normal values being statistically determined values reported by the California Department of Water Resources (DWR).

DWR defined all of these values. This information on is documented in Attachment A and summarized in Table 2.

Reference evapotranspiration (ET) for each month is based on long-term monthly average ET values for the Plymouth California Irrigation Management Information System (CIMIS) Station #227, located approximately 13 miles northeast of the golf course. This information is documented in Attachment A of this TM and summarized in Table 2, along with the monthly total rainfall values for the average and 1-in-100 rainfall years.

¹ CDPH has since been incororpated into the State Water Board as the Division of Drinking Water (DDW).

Table 2. Applicable Climate Data								
Month	Average Rainfall, (a) inches	1-in-100 Year Rainfall, (a) inches	Reference ET, ^(b) inches					
October	1.15	2.15	3.24					
November	2.81	5.24	1.68					
December	3.54	6.58	1.21					
January	5.09	9.48	1.48					
February	3.14	5.86	1.95					
March	3.20	5.95	3.02					
April	1.75	3.26	4.57					
May	0.63	1.18	5.97					
June	0.23	0.43	7.19					
July	0.07	0.13	7.64					
August	0.13	0.24	6.98					
September	0.33	0.62	4.99					
Total	22.1	41.1	49.9					
· ·	22.1	1						

Crop ET

Monthly crop ET values for the golf course were calculated by multiplying the reference ET values from Table 2 by a representative crop coefficient. Grasses grown on the golf course include:

- perennial rye grass
- poa annua
- creeping bent grass
- tall fescue
- Bermuda grass

Apart from Bermuda grass, all grasses used on the golf course are considered cool season grasses. Meyer and Gibeault at the University of California, Irvine report monthly crop coefficients for cool season grasses (see of Attachment B). The average of these reported monthly crop coefficients for April to October, calculated to be 0.88, was used as a representative crop coefficient for all months.

Pond ET

Monthly ET values for the storage pond Lake I were set equal to the respective monthly reference ET values.

Historical Recycled Water Demands

Evaluation of historical recycled water demands was based on the following:

- To properly maintain the golf course greens, recycled water is delivered to the COWRF and golf course solely based on golf course demands.
- Golf course flow data is tracked by golf course staff, and total monthly and annual flow volumes based on this data are shown in Table 3.
- The historical average volume of recycled water delivered was calculated for each calendar month
 and was used to calibrate and confirm the theoretical recycled water demand for the golf course.

	Table 3. Historical Golf Course Recycled Water Demand									
	Volume of Recycled Water Used, million gallons (MG)									Average,

⁽a) Values excluded from average calculation. The COWRF influent flow meter failed on October 9, 2024 and COWRF staff requested that water be sent to the COWRF at a steady rate of 800 gallons per minute until the end of the irrigation season in mid-November.

Therefore, during this period, there was less ability to match the effluent flows from the COWRF to golf course agronomic demands and it is not clear these are representative values.

Theoretical Recycled Water Demands

Theoretical recycled water demands for the golf course were developed based on the following:

• Theoretical agronomic demands are calculated by multiplying the difference between the calculated monthly crop ET and monthly rainfall values by the total area of the golf course (130 acres) and dividing by an irrigation efficiency factor. For months with more precipitation than ET, the irrigation demand was set equal to zero.

⁽b) Values excluded from average calculation. There was limited recycled water supply available from ARSA during the period of May to June 2022 and the golf course was under-irrigated.

⁽b) Value is excluded from average because it is anomalous when compared with September recycled water use volumes of other years. Operations staff responsible for this data are not available to confirm its accuracy.

- Irrigation efficiencies for solid set spray irrigation systems like that used on the golf course can range from 60 to 85 percent (see Attachment C, Table 8.2b). A calibration process, described in the next section, has been used to define the irrigation efficiency for this site.
- Theoretical evaporative losses from the storage ponds are calculated by multiplying the difference between the reference ET and monthly rainfall values by the total area of the impoundment.
- As noted previously, recycled water is only sent to and pumped from Lake I. Therefore, evaporative losses from only Lake I (3.1 acres) are included.
- Losses are calculated for months only when recycled water is delivered to the golf course.
- There have been no attempts to quantify percolation losses from Lake I. Therefore, percolation losses are assumed to be zero.
- Total theoretical recycled water demands are the sum of the theoretical monthly golf course agronomic demands and the theoretical monthly evaporative losses from Lake I.

Average Year Theoretical Recycled Water Demand Calibration

The site-specific irrigation efficiency factor used to calculate the theoretical irrigation demand is determined by adjusting the irrigation efficiency value used in the calculation of the average-year theoretical recycled water demand until the demand matches the historical recycled water supplied.

The resulting irrigation efficiency is 84 percent, on the upper end of the typical range for spray irrigation cited above. *This calibration process demonstrates that the golf course irrigation system is very efficient and experiences limited losses.*

1-in-100 Year Recycled Water Demand

The 100-year theoretical recycled water demand is calculated using the procedures described above but applying 1-in-100-year rainfall values and retaining the 84 percent irrigation efficiency determined from the average year water balance.

Agronomic Water Demands

The calculated average rainfall year theoretical demand to be used in the water balance analysis is shown in Table 4. The calculated average 1-in-100-year theoretical demand to be used in the water balance analysis is shown in Table 5.

The historical data show irrigation demands in November, but the theoretical demands do not indicate a need for irrigation water in this month. This discrepancy likely reflects the fact that rainfall typically does not begin until late November in this area, while there are still irrigation demands earlier in the month. Despite this discrepancy, the annual theorical demand matches closely to the historical values for the average year. Therefore, the methodology applied provides an accurate estimate for purposes of developing an annual water balance for COWRF.

COWRF INFLUENT FLOWS

Calculation Procedures

The theoretical influent flow to the COWRF is calculated for each month using the following formula:

Golf Course Irrigation Demand/(1-backwash percentage)

The Golf Course Irrigation Demands were discussed in the previous section. The backwash percentages are calculated based on historical COWRF influent and backwash flow data, as described in the sections below.

Historical COWRF Influent Flows

Historical monthly influent flows to the COWRF are shown in Table 6. Influent flows beginning in April 2022 are reported in the monthly COWRF discharge monitoring reports (DMRs). Prior to 2022, COWRF DMRs did not present influent flows. However, the influent flows were determined from available golf course demand data and backwash flow data.²

Table 6. Historical COWRF Influent Flows									
			Vol	ume of CO	OWRF Influ	uent Flow,	MG		
Month	2017	2018	2019	2020	2021	2022	2023	2024	Average
October	19.5	10.3	20.7	17.9	10.5	10.9	19.2	27.7 ^(a)	17.1
November	0	4.8	15.8	7.8	0	11.3	9.3	4.0 ^(a)	8.8
December	0	0	0	0	0	0	0	0	0
January	0	0	0	0	0	0	0	0	0
February	0	0	0	0	0	0	0	0	0
March	0	0	0	0	0	2.0	0	0	2.0
April	0	0	0	0.9	14.4	12.7	2.1	0	7.5
May	20.4	21.6	17.1	16.8	29.1	14.0 ^(b)	18.8	19.8	19.7
June	29.1	30.1	23.7	23.0	24.7	13.1 ^(b)	25.8	32.0	25.2
July	34.1	33.5	31.2	30.2	35.7	23.1	29.5	32.1	31.2
August	33.3	36.9	33.3	30.1	27.0	23.2	27.4	32.3	30.3
September	27.1	27.7	28.1	20.2	11.2 ^(b)	18.5	21.4	28.0	22.8
Total, MG	163.4	164.9	169.7	146.7	152.7	128.8	153.5	174.7	164.5

⁽a) Values excluded from this evaluation. The COWRF influent flow meter failed on October 9, 2024. Reported influent is an estimate of the actual flow received during this period.

WEST YOST

N-C-988-50-24-10 AS NEEDED-WP

-

⁽b) Although values reported in these months are not representative of typical influent flows (and thus irrigation demands), they are useful in determining the percentage of backwash flow generated. Therefore, these values are not excluded from this portion of the analysis.

² To determine influent flows prior to April 2022, monthly COWRF effluent flows from the DMRs were compared to golf course flows and filter backwash flows. If the reported COWRF effluent flow was larger than the golf course flow, it was confirmed to be actual influent flow by verifying that it was equal to the sum of the golf course influent flow and the filter backwash flow. If the reported COWRF effluent flow was equivalent to the golf course flow, the COWRF influent flow was calculated by summing the COWRF effluent flow and filter backwash flow. The 2017 COWRF influent flows were calculated by summing monthly golf course influent flows and filter backwash flows because COWRF DMRs were not available.

Historical COWRF Backwash Flows

Historical monthly filter backwash flows from the COWRF are shown in Table 7.

Table 7. Historical COWRF Filter Backwash Flows									
			Volum	ne of COW	RF Filter B	Backwash Fl	ow, MG

⁽a) Values were not used in calculated average. Operations staff were performing excessive backwashing of the filters. This practice has since ceased.

Filter Backwash Flow Percentages

The percentage of COWRF influent flow that was discarded as backwash flow to the WWTF each month was calculated by dividing the backwash flow by the influent flow. Table 8 shows the results of this calculation. From the percentages shown, a monthly average was calculated. Monthly average backwash percentages range from 13 to 20 percent.

Table 8. Historical COWRF Filter Backwash Flow Percentage

		Filter Backwash Flow as a Percentage of Influent Flow, percent							
Month	2017	2018	2019	2020	2021	2022	2023	2024	Average

September	15	13	14	20	23	12	30 ^(a)	20	17

- (a) Values were not used in calculated average. Operations staff were performing excessive backwashing of the filters. This practice has since ceased.
- (b) Values excluded from this evaluation. The COWRF influent flow meter failed on October 9, 2024. Reported influent is an estimate of the actual flow received during this period.
- (c) "-" indicate there were no flows to the COWRF during this period.
- (d) The backwash percentage during April 2023 was abnormally low. Influent flow to the COWRF began six days before the end of the month and effluent and backwash were only discharged on two of the six days. This value was not used in the calculated average.

Theoretical COWRF Influent Flow

The calculated average rainfall year theoretical flow to the COWRF to be used in the water balance analysis is shown in Table 9. The calculated average 1-in-100-year theoretical flow to the COWRF to be used in the water balance analysis is shown in Table 10.

Theoretical COWRF Backwash Percentages and Flows

A calculated theoretical backwash flow from the COWRF to the WWTF will be used in the water balance analysis for the WWTF, based on the influent flows from Table 9 and Table 10 and average historical backwash flow percentages by month from Table 8. The theoretical COWRF backwash flow for an average rainfall year is shown in Table 11. The theoretical COWRF backwash flow for a 1-in-100 rainfall year is shown in Table 12.

GOLF COURSE TAILWATER AND OVERSPRAY CONTROL AND MONITORING

This section provides information about Best Management Practices (BMPs) and monitoring for tailwater and overspray control from the golf course. The following topics are addressed:

- Golf Course Field Monitoring
- Golf Course Best Management Practices
- Golf Course Storage Pond Monitoring

Golf Course Field Monitoring

The City, in coordination with the golf course management, is required to perform daily, weekly, and monthly monitoring of the golf course when recycled water is being applied, as outlined in the WRR's Monitoring and Reporting Program (MRP). These requirements are summarized in Table 13. In addition to the elements outlined below, the daily inspections must note any evidence of erosion, field saturation, runoff or the presence of nuisance conditions.

The MRP was adopted December 21, 2021, and did not become effective until after the end of the 2021 irrigation season. Since its adoption, the MRP requirements related to the golf course operations shown in Table 13 have not been satisfied. The City and golf course staff are currently developing the protocols to implement this monitoring and will initiate the program beginning in the 2025 irrigation season.

⁽c) = Column 1 x Column 2

Table 13. Golf Course Monitoring Requirements										
Constituent	Units Type of Sample Sampling Frequence		Sampling Frequency	Reporting Frequency						
Flow	gallons	Continuous								
Rainfall ^(a)	inches			NA the bar						
Acreage Applied ^(b)	acres	Calculated	Daily	Monthly						
Tailwater Runoff Observation		Observation								
(a) As measured at the weather station nearest to the disposal site. (b) Specific disposal fields shall be identified.										

Flow

Currently, golf course staff monitor the daily total flow that is applied to the golf course. This flow is measured from the irrigation pump station and recorded in the golf course's central computer system. The measurement can be reported in up to 15-minute increments. Golf course staff report the daily total flows to the City.

Rainfall

Rainfall collects in a plastic rain gage located at the maintenance yard, and golf course staff manually read the gage daily at approximately the same time of day. That measurement is compared to a reported weather station located in the nearby City of Jackson to confirm its accuracy. The onsite, measured rainfall data is reported to the City.

Acreage Applied

The golf course's central computer system has the ability report the areas that are watered each night. These areas are grouped and reported by area category according to the type of plant that is watered. The area categories are:

- Greens
- Tees
- Fairway
- Perimeter
- Rough
- Club House
- Driving Range
- Putting Green

Irrigation generally occurs on all areas of the golf course simultaneously. In rare instances an area category may be watered alone. Starting with the 2025 irrigation season, golf course staff will report the acreage that is watered daily and include that information in the flow report provided to the City monthly.

Tailwater Runoff Observation Monitoring

Starting with the 2025 irrigation season, City staff will inspect the golf course daily for evidence of runoff and overspray. These inspections will occur in the morning, just after irrigation occurs. During these inspections, special attention will be paid to the following five vulnerable areas, which have the most potential for recycled water to escape the use area:

- Castle Oaks Clubhouse
- Areas abutting Mule Creek
- Spyglass Drive near the Irrigation Pump Station
- Castle Oaks Drive and Shakeley Lane intersection
- Near the bathroom by Vista Lane

Monitoring each location will be done through an observatory drive by each location in the early morning. Evidence of runoff or overspray includes wet areas on hardscape sidewalks and roadways surrounding the extents of the landscaped area. If these areas are wet or water appears to be draining from landscape into the gutters, the irrigation system should be further investigated for problems. Inspection logbook entries for the golf course monitoring will be submitted with the monthly monitoring reports.

Golf Course Best Management Practices

Overspray and runoff of recycled water from the use area is minimized and controlled through the implementation of BMPs. Spray irrigation systems are vulnerable to inefficiencies related to runoff or overspray caused by pressure fluctuations, wind, or equipment malfunction. If any part of the system is not working optimally, the result is a less uniform application of water which increases the likelihood of water escaping the recycled water use area. Even the most efficiently designed system must be maintained and constantly monitored to mitigate system avoid problems.

The COWRF BMP strategies include engineered controls and mechanisms to minimize runoff or overspray and practices to improve the application of water to a use area. Specific BMPs employed to control for runoff or overspray include:

- Irrigation is ceased during extended and extensive windy periods.
- Irrigation is avoided when the soil is saturated to prevent runoff.
- All sprinkler heads are uniform in brand, model and nozzle size to apply water as uniformly across the plant material as possible.
- A minimum four-foot distance from neighboring backyards and buildings is maintained as
 practical throughout areas of the golf course. This has been done through head removal, spray
 range or arc reduction or elimination of a zone. In areas where the four-foot buffer cannot be
 maintained and irrigated turf is desired, such as near a tee, hole or walkways, the irrigation water
 is applied with lower impact heads with a smaller arc radius.
- Irrigation occurs in the evening or early morning hours to avoid public interaction, reduce evaporative loses, and take advantage of calmer wind patterns.
- Good horticultural practices are performed including, mowing, de-thatching, aeration, and pest control as necessary to increase the plant and soil water absorbance.
- Irrigation is applied as close as practical to match the amount of water lost through ET and the soil needs.

TM – City of Ione December 10, 2024 Page 23

- Duration of water application is applied to match percolation rates to reduce runoff.
- Installation of low angle heads have been installed in areas near residential backyards to reduce mist from wind drift of spray.
- Tall plants are present along edges and perimeters to create a plant buffer.
- Regular maintenance is performed of the irrigation system which includes inspecting and repairing leaks.

Golf Course Storage Pond Monitoring

Monitoring of irrigation storage ponds when they contain recycled water is also required under the MRP. These requirements are summarized in Table 14.

Table 14. Golf Course Storage Pond Monitoring Requirements											
Constituent	Units	Type of Sample	Sampling Frequency	Reporting Frequency							
Freeboard	feet	Measurement	Twice Weekly – 3 days apart								
Odors		Observation	Weekly	N.A. a. a. t. la .							
Dissolved Oxygen	milligrams per liter	Grab	Weekly	Monthly							
рН	pH units	Grab	Monthly								

Similar to the irrigation area, the MRP requirements related to the ponds have not been consistently satisfied. The City and golf course staff are currently developing the protocols to implement this monitoring and will initiate the program beginning in the 2025 irrigation season.

Freeboard

The MRP requires the freeboard be monitored as the difference between the top of the bank of the storage pond to the level of the water. This measurement provides the City with confidence that recycled water cannot escape the storage pond containment area. However, as noted previously, each pond is equipped with a standpipe that serves as an overflow structure. Therefore, it is more appropriate to monitor freeboard as the difference between the top of the overflow structure to the top of the water surface.

Currently, the City has the ability to measure the freeboard of Lake A by means of a level monitoring rod. This capability is not set up in Lakes B through I. Lake I is manually kept at a level that is below the 12-inch overflow standpipe that conveys overflow water to a wetland area that eventually flows to Mule Creek. Prior to the start of the 2025 irrigation season, the City will need to install a level monitoring rod in each pond so that freeboard can be measured.

In addition, the City will employ the following monitoring practices in the 2025 irrigation season:

- Twice a week during the irrigation season, each storage pond should be observed, and freeboard monitored.
- For Pond I, it is expected that there will be recycled water present in the pond throughout the irrigation season and this pond should be monitored during each bi-weekly event.

- Recycled water is occasionally directed to Pond A. Therefore, this pond will be inspected as part
 of the bi-weekly monitoring. If there is standing water present in Pond A, then monitoring of this
 pond will be completed.
- If there is any evidence that Pond A has overflowed to Pond B (or any downstream pond) via the pond standpipes, then monitoring of the downstream ponds will also be performed.
- City staff will be responsible for making the appropriate observations to determine whether recycled water is being stored in any of the ponds.
- Golf course staff will provide information to the City regarding where COWRF flows are directed.
 Specifically, the monthly reports provided to the City will include information about which pond was receiving flow on each day.

Odors

The City is required to evaluate if any objectionable odors are being emitted from the storage ponds once every week. This will be needed for each pond that holds recycled water.

Dissolved Oxygen and pH

The City is required to collect and measure the dissolved oxygen and pH in a grab sample collected from each recycled water storage pond weekly. These measurements can be made using field test instruments provided that:

- The operator is trained in proper use and maintenance of the instruments,
- The instruments are field calibrated at the frequency recommended by the manufacturer,
- The instruments are serviced and/or calibrated at the manufacturer's recommended frequency, and
- Field calibration reports are maintained and a calibration log verifying calibration of all handheld monitoring instruments and devices are submitted with the monthly monitoring report.

Turfgrass Performance Under Reduced Irrigation Meyer and Gibeault

Turfgrass performance under reduced irrigation

Jewell L. Meyer

Victor A. Gibeault

urfgrass in California requires irrigation during all or most of the year. Water restrictions imposed during the drought in 1976 and 1977 forced turf managers to reexamine many concepts about irrigation. Turfgrass managers had to make drastic cuts in water use and hope that the turf would survive. One significant result of the drought was the realization that lower levels of turf quality were acceptable in many situations and that large water savings could be achieved. No information was available, however, on the best conservation practices or on the minimum amounts of water needed to keep the turf alive.

Research was begun in 1979 to produce irrigation methodology that could be used to develop water-saving irrigation practices anywhere in California and in other arid and semiarid regions. The three-year study showed that major savings of water can be achieved, especially with warm-season grasses, with no appreciable loss of turf quality.

Turf-irrigation study

Specifically, the objectives of the research were to: (1) investigate the effects of applying reduced amounts of irrigation water calculated as a percentage of evapotranspiration of applied water on coolseason and warm-season turfgrasses; (2) evaluate a below-ground system as a po-

tentially more efficient method of turf irrigation than standard sprinkler application; and (3) develop a set of crop coefficients that California turfgrass managers can use to determine on-site water use by both cool- and warm-season turfgrasses.

The study was conducted at the University of California South Coast Field Station, Irvine. The variables tested included: two irrigation methods, sprinkler application of water and a subterranean or buried trickle/drip water application (8-inch depth, 23-inch spacing); three irrigation regimes, 100, 80, and 60 percent of calculated evapotranspiration; and six commonly used turfgrasses, three coolseason varieties (Kentucky bluegrass, perennial ryegrass, and tall fescue) and three warm-season types (hybrid bermudagrass, zoysiagrass, and Seashore Paspalum).

The field plot was a randomized splitblock design. The area was divided into two turf blocks, one for cool-season grasses and the other for warm-season grasses. Each block consisted of four replications, and within each replication were six randomized irrigation plots measuring 15 by 24 feet. Irrigation plots were divided into three turf subplots of 8 by 15 feet. The three sprinkler and three subterranean irrigation plots per replication were installed in September 1979 for

above- and below-ground water application. Each sprinkler irrigation plot contained six high-pop brass sprinkler heads designed to apply 10 gallons of water per minute at a pressure of 35 pounds per square inch. The coefficient of uniformity was 87 percent.

Tensiometers at 3- and 6-inch depths in the cool-season grasses and 8- and 12-inch depths in the warm-season grasses indicated soil water status; neutron probe access tubes were installed in plots to a depth of 4 feet in the cool-season and 6 feet in the warm-season grasses. Scheduling was by the water budget technique calculated weekly using wind-modified pan evaporation data. State-of-the-art controllers were programmed with this irrigation scheduling information. The amount of irrigation was modified so that water did not pass below the 4-foot and 6foot depths of the neutron probe access tubes during the irrigation season.

Annual crop coefficients, determined from previous research using applied water and evaporation pan data, were 0.7 annually for warm-season grasses and 0.8 for cool-season grasses. Monthly crop coefficients were developed in this experiment to evaluate responses of the six turfgrass species to 60 percent and 80 percent of replacement evapotranspiration for water conservation.

Turf performance

Overhead sprinkler irrigation provided acceptable performance of some turfgrass species, even when less than the optimum amount of water was applied. Subterranean irrigation did not provide acceptable turf with the shallow-rooted cool-season species, at the system depth and spacing used in this study. The very deeply rooted hybrid bermudagrass was the best-performing species with subterranean irrigation.

Under sprinkler irrigation, there was no significant difference in cool-season grass performance between the 100 percent and 80 percent regimes (table 1). This could be described as a potential level of water conservation amounting to 21.1 percent savings (77.2 inches versus 61 inches). The savings could be tenuous, however, because of more weed and disease activity (such as Gerlachia patch on Kentucky bluegrass) when irrigated with less than the optimum amount of water. The 60 percent regime significantly reduced the turf quality of the three coolseason grasses tested.

In the warm-season grasses, the appearance of hybrid bermudagrass and Seashore Paspalum was not significantly different under any of the irrigation regimes. As irrigation amounts were reduced, zoysiagrass appearance ratings declined because of nematode activity observed on the roots. Both Santa Ana hybrid bermudagrass and Adalayd (Excalibre) Seashore Paspalum had very good color, density, texture, uniformity, and freedom from weeds and diseases, irrespective of irrigation regimes. Clearly there is potential for considerable water savings with these grasses. This study showed a 40 percent reduction in actual water applied between the optimum and lowest irrigation regime (65.5 versus 39 inches).

Because of the field plot design necessary for this study, it wasn't possible to compare statistically the turf performance results between the warm- and cool-season grasses. Hybrid bermuda and Seashore Paspalum performed very well, however, with 52.7 inches of water applied (60 percent irrigation regime), whereas the cool-season grasses needed at least 82.4 inches (80 percent irrigation

regime). Thirty-six percent less water was applied to the warm-season species than to the cool-season species for acceptable turf quality. If applied water in the 60 percent irrigation treatment in warmseason grasses (52.7 inches) is compared with that in the 100 percent treatment in cool-season grasses (104.4 inches), the saving in water is 49.5 percent.

Water application

The cool-season grass in the 100 percent regime received 43 inches of water in 1982 (table 2). Warm-season grasses received only 34 inches. Rainfall of 18.45 inches occurred primarily from November to March. The soil profile held about 10 inches depth of water in the top 6 feet. Rainfall did not appreciably affect the applied water during the primary growing season, April through November. Likewise, the 34 inches applied to the warm-

season grasses was not appreciably affected by, nor was there evidence of, deep percolation during the primary growing season, when only 4 inches of rain fell. The rainfall is subtracted from the original evaporation pan reading and is therefore reasonably accounted for in the calculated applications.

In 1983, a higher than normal rainfall of 32 inches occurred. The soil profile was filled during the winter, however, and only 9 inches of rain fell from April to October 30, of which 4 inches occurred in early April. Water moved below the root zone only on June 29, August 29, October 5, and October 17 in all plots of 100 and 80 percent irrigation in 1983. Even during a season of higher than normal rainfall, the applied water, 38.7 inches in cool-season grasses (1983), was similar to that of the drier year (1982) with 43 inches applied. Most of the 5 inches of implied higher use by cool-season grasses may have moved through deep percolation.

The water applied to warm-season grasses was 34 inches in 1982 and 33 inches in 1983. This small difference indicates that managers can schedule carefully and conserve water in a wet or dry season.

Conclusions

The monthly crop coefficients (table 3) calculated and used for nearly three years proved to be very accurate for both warm- and cool-season turfgrasses. Crop coefficients can be used with reference evapotranspiration from the Department of Water Resources California Irrigation Management Information System (CI-MIS) program. Turfgrass managers can use these crop coefficients to determine on-site water use by turfgrasses from either a Class A Weather Bureau evaporation pan or from a computerized weather station that gives reference evapotranspiration with the equation given in table 3.

In conclusion, warm-season turfgrasses have a greater potential for water conservation than do cool-season turfgrasses. Under the conditions of this study, sprinkler irrigation was superior to subterranean irrigation for water conservation and turfgrass performance. And lastly, a well-designed, uniform irrigation system is necessary to maximize water conservation in turfgrass management.

Irrigation Chapter 8 - Irrigation Efficiencies

Author: Bill Kranz, University of Nebraska Lincoln Extension Irrigation Specialist, Northeast Research and Extension Center, Norfolk, NE.

Water Application Efficiency

The ability to manage an irrigation system is contingent on an accurate estimate of the percentage of water pumped that becomes available for crop use. No irrigation system delivers water at 100 percent efficiency. Water may be lost through delivery systems or pipelines and some water may remain in the soil, but not be used by the crop. Some water may run off the soil surface into lowland areas. Still other water may be lost to evaporation in the air, or from the soil and plant surfaces. Figures 8.1a and 8.1b show the major losses for sprinkler and surface irrigation systems. To know how much water to pump, these losses must be totaled and added to the amount of water needed by the crop.

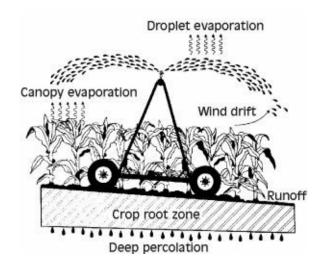

Figure 8.1. a) Potential water losses during irrigation with a center pivot. b) Potential water losses during irrigation with a furrow irrigation system.

In most cases, the goal is to insure that all areas of the field receive a set amount of uniformly applied water. Consider the catch can test data shown in Figure 8.2. The cans recording application depths below the horizontal line are not receiving enough water — catches are less than the desired 0.85 inches. Another application will be needed to insure that the entire field receives at least 0.85 inches of water. This will require using more water and energy than is necessary. If this pattern occurs during each irrigation, plants in the areas receiving less than 0.85 inches eventually could experience water stress. The cans recording application depths above the line receive at least 0.85 inches of water. Any extra water applied could lead to surface runoff or deep percolation.

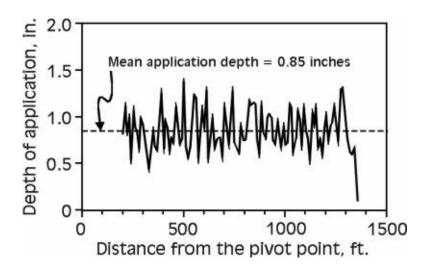

Figure 8.2. Example of catch-can data from a center pivot with low pressure spray nozzle, mounted at 10 foot intervals and 7 feet above the soil surface.

Water application efficiency accounts for how uniformly the water is applied and can be used for other assessments. If the center pivot owner is trying to decide whether switching to a new sprinkler package would be economical, the change in water application efficiency could be a major factor. If water becomes limited, changing to a system with a higher water application efficiency will provide more useable water to the crop and reduce pumping costs.

To maximize irrigation water use, it must be uniformly applied in the right amount and at the right time. Reaching these objectives requires knowledge of water delivery characteristics, field soils and slopes, and the expected crop water use rates.

Mathematical relationships have been developed to help quantify the amount of applied water that becomes available for plant use.

Water application efficiency refers to the amount of water applied that is stored in the crop root zone. This value is determined by water distribution characteristics, system management, soil conditions, the crop, and weather conditions. Water application efficiency pertains to an individual irrigation event.

Equation 8.1 is used to determine water application efficiency.

Equation 8.1 $E_a = [\underline{Depth\ of\ water\ stored\ in\ the\ rootzone\ (d_s)\ x\ 100}]$ water pumped (d_p)]

Depth of

where:

 E_a = Average water application efficiency, %

Depth of water stored in the rootzone (d_s) = Average depth of water stored in the rootzone, inches

Depth of water pumped (d_p) = Average depth of water delivered from source, inches

Irrigation efficiency refers to the amount of water removed from the water source that is used by the crop. This value is determined by irrigation system management, water distribution characteristics, crop water use rates, weather and soil conditions. Irrigation efficiency pertains to the use of water for an entire growing season.

Depth Stored

The depth of water stored in the root zone can be estimated based on field observation of what happens to the water during an application event. Field observation reports should note if runoff occurs and estimate the amount of runoff. With experience, you'll begin to know where and when runoff is likely to occur. For example, runoff from center pivot systems will likely occur first near the outside edge of the irrigated area because the water application rate is greatest there. Other factors include low **infiltration** rate soils, steep slopes and lack of plant residue cover.

Another more accurate method is to record the <u>soil water</u> content before and after an irrigation event using one of the methods discussed in *Chapter 3, Soil Water*. If the hand-feel method is used, the <u>soil water content</u> will need to be recorded at enough locations to develop accurate estimates of the water stored in the crop root zone. The depth of water applied is found by subtracting the reading taken before the irrigation.

```
Equation 8.2 d_s = ["After" reading - "Before" reading]
```

Where:

d_s = Depth of water stored in the rootzone

Example 8.1

A center pivot irrigation system is supplied with enough water to apply 1.1 inches of water to an irrigated area. Soil water content readings recorded before the irrigation event showed an average water content of 3.5 inches in the top 3 feet of soil. Soil water content readings after the irrigation showed an average of 4.4 inches in the top 3 feet of soil. To find the average depth of water stored in the crop rootzone we subtract the before irrigation reading from the after irrigation reading.

```
Using Equation 8.2 d_s = ["After" reading - "Before" reading]
d_s = [4.4 inches - 3.5 inches]
d_s = 0.9 inches
```

Depth Pumped

The depth of water pumped can be determined using the procedures presented in *Chapter 7, Flow Measurements and Basic Water Calculations*. The information needed includes an accurate estimate of the pumping rate in gallons per minute. This information can be recorded using a flow meter installed as part of the system or periodically using an attached flow meter (ultrasonic flow meter, pilot tube type meter, etc.).

The average flow rate can be determined by recording the accumulator reading prior to and after each irrigation event. Subtracting the reading recorded prior to the irrigation from the reading after the irrigation event will result in the total volume of water pumped. Taking the total volume and dividing by the irrigation time will give the average pumping rate. For this estimate to be accurate, the irrigation time must be accurate to the nearest hour if possible. A more precise record of the total irrigation time will improve the estimate of the pumping flow rate. (The hour meter on the motor or center pivot is accurate enough to estimate the pumping time.) *Equations 8.3* and *8.4* are used to make these calculations. The following example shows how to incorporate field data into the equations.

```
Equation 8.3 Pumping rate = [Reading 2 - Reading 1]/[Time] where:
```

Pumping rate = Water deliver rate, gallons per minute or acre-inches per minute

Reading 1 = Totalizer reading before the irrigation event, gallons or acre-inches

Reading 2 = Totalizer reading after the irrigation event, gallons or acre-inches

Time = Time required to complete the irrigation event, minutes

Example 8.2

The meter also has an accumulator at the bottom that registers total gallons pumped. Before the irrigation event, the accumulator reading was 6,553,300 gallons, and after the irrigation event the meter read 10,167,500 gallons. The irrigation event required 77 hours and 15 minutes.

Using Equation 8.3

Pumping rate = [Reading 2-Reading 1]/[Time]

Pumping rate = [10,167,500 - 6,553,300] gallons [(77 hr x 60 min/hr) + 15 min]

Pumping rate = [3,614,200] gallons / [4620 + 15] minutes

Pumping rate = 780 gallons per minute

If the accumulator records flow in acre-inches, the same process is used unless the desire is to determine the flow rate in gallons per minute. To convert acre-inches per minute to gallons per minute, multiply the result from *Equation 8.3* in acre-inches per minute by 27,154 gallons per acre-inch.

To convert the flow rate in gallons per minute to the gross depth of water pumped, we use *Equation 8.4*. If the result from *Equation 8.3* is in acre-inches per minute, the constant 27,154 gallons per acre-inch is not used.

Equation 8.4 $d_p = [flow \ rate \ x \ time] / [area \ irrigated \ x \ 27,154]$

where:

d_p = Depth pumped = Average depth of water pumped, *inches*

Flow rate = Average water delivery rate, gallons per minute

Time = Total irrigation time, minutes

Area irrigated = Total irrigated area, acres

27,154 = Conversion factor, gallons per acre-inch or gal / ac-in

Example 8.3

Let's assume that the field area for Example 8.2 was 123 acres. We calculated the flow rate at 780 gallons per minute and the total irrigation time at 4635 minutes. Using *Equation 8.3*:

```
Depth pumped (d_p) = [Flow rate x time] / [Area irrigated x 27,154]

Depth pumped (d_p) = \underline{[780 \ gal/min \times 4635 \ minutes]}

[ 123 acres x 27154 gal / ac-in]

Depth pumped (d_p) = [3,615,300] gallons / [3,339,942] gallons / inch
```

Depth pumped $(d_p) = 1.08$ inches

To complete the calculation of the water application efficiency, use *Equation 8.1* to compare the amount of water pumped with the increase in water stored in the crop rootzone.

Example 8.4

From Example 8.1 we found that 0.9 inches of water was stored in the three-foot crop rootzone. From Example 8.3 we found that 1.08 inches of water was pumped from the water source into the center pivot. To find the application efficiency we use *Equation 8.1*.

 $E_a = [\underline{Depth \ of \ water \ stored \ in \ the \ rootzone \ (d_s) \ x \ 100}]$ Depth of water pumped (d_p)

 $E_a = [0.9 \text{ inches} / 1.08 \text{ inches}] \times 100$

 $E_a = 83\%$

In these examples it was determined that only 83 percent of the water pumped from the irrigation source reached the soil and was usable by the crop. That means that 17 percent of the water was lost during application.

Potential Delivery Losses

The amount of water loss due to irrigation depends of the type of irrigation system — sprinkler or surface. In addition, the magnitude of each type of loss may be different. Let's begin by listing some major sources of water loss during irrigation. To keep the losses for surface and sprinkler irrigation separate, *Table 8.1* lists the potential losses for each type of system.

Table 8.1. Potential sources of water loss during an irrigation event for surface and sprinkler irrigation systems.

Sources of water losses	Surface Irrigation	Sprinkler irrigation
Distribution system	Yes	Yes
Air evaporation	No	Yes
Plant interception	No	Yes
Soil evaporation	Yes	Yes
Deep percolation	Yes	Yes
Runoff	Yes	Yes

Surface Irrigation Systems

The major losses for surface irrigation systems are deep percolation and surface runoff. These two losses could cause the water application efficiency to be reduced to less than 50 percent if the system is not managed properly. Ways to minimize these losses are discussed in <a href="https://www.lo.go.nlm.nimizeth.nim

(https://passel2.unl.edu/view/lesson/bda727eb8a5a/11).

Another source of water loss is in the distribution system. If the water flows across the head of the field in an open ditch, each foot of ditch loses water to soil infiltration and water surface evaporation. The best way to eliminate these losses is to transport the water through an enclosed pipeline. For many furrow irrigated fields this will require a small pumping plant to overcome the friction loss associated with forcing water through the pipeline.

Surface irrigation implies that surface evaporation will contribute to water loss. One way to limit soil evaporation loss is to wet less of the soil surface. For fields with slopes less than 1 percent, irrigating every other furrow is a viable option. This effectively cuts surface evaporation losses by nearly 50 percent without sacrificing crop production. Irrigating every other furrow also will reduce the amount of water lost to deep percolation and surface runoff.

Pipelines can have losses too. Worn gaskets or loose fitting pipeline connections could produce leaks at each joint. These losses are usually small in comparison to other losses, but by their sheer number could add up to substantial water losses. This kind of loss is the easiest to eliminate by replacing gaskets.

Sprinkler Irrigation Systems

Sprinkler irrigation systems, especially center pivots, typically have greater water application efficiencies than surface systems. While they may have more potential sources of loss, the magnitude of each loss is generally quite low. *Table 8.1* shows that sprinkler irrigation systems may experience loss from all six of the potential water loss sources while surface irrigation systems lose water from only four. This is because most sprinkler irrigation systems spray water into the air to deliver water to the entire soil surface with an upright crop canopy located between the sprinkler and soil.

Developments in sprinkler technology have reduced the amount of water lost between the sprinkler/nozzle and soil surface. The irrigation time or the accumulated time that water is applied to the crop canopy causes the major loss during sprinkler irrigation events. Applied water evaporates off the leaves of the crop canopy. Thus, the longer water droplets are delivered to the crop, the greater the total evaporation loss. Lowering the sprinkler/nozzle pressure reduces the wetted diameter of the sprinkler/nozzle thus reducing irrigation time and total canopy evaporation losses. In addition, lower wetted diameters reduce water evaporation losses in the air and wind drift losses.

Proper management of sprinkler irrigation systems can greatly reduce deep percolation losses. An irrigation system managed to keep the soil profile completely full at all times will experience some deep percolation losses. This is because the system does not apply water at 100 percent uniformity. Some areas will receive more water than others due to sprinkler pressure differences caused by soil elevation differences. Pressure regulators or flow control nozzles help insure that water delivered to the soil surface is as uniform as possible. Other portions of the field could be affected when wind distorts the water application pattern. Such distortion can be reduced by avoiding operation when winds exceed 10 mph.

How do I Evaluate Losses?

There are two main ways to evaluate water loss during irrigation: 1) take detailed field measurements; and 2) visually estimate losses. In some cases it may be necessary to combine these methods to develop an accurate estimate of where losses occur and how significant they are to the system's application efficiency. For example, to estimate water losses during irrigation, measure the flow rate of water entering the system with a flow meter. Visually estimate how much of the water is lost to runoff. This amount, however, will not account for other potential losses. *Table 8.2* presents the potential magnitude of some of these losses for different irrigation systems. For furrow irrigation systems record how long it takes for the water to reach a certain point in the field or record flow rates into the furrow and how long it takes water to reach the end of the furrow. When coupled with soil types and furrow slopes, a computer model can be used to estimate how efficiently the water is being applied.
